

## MapStore

MapStore is an highly modular **Open Source** WebGIS framework developed by GeoSolutions to create, manage and securely share maps and mashups. This simple and intuitive framework is able to mix map contents provided by Google Maps, OpenStreetMap, Bing or other servers compliant to OGC standards like WFS, CSW, WMC, WMS, WMTS and TMS. MapStore is used to find, view and query published geospatial data and to integrate multiple remote sources into a single map; the result is an high quality and user friendly framework that allows different kind of use cases by harmonizing remote data with smart and advanced functionalities (like chart widgets, dashboards, timelines and others). MapStore resources are not only related to Maps but also Dashboards and Stories; in MapStore you can create your own innovative and fascinating Application Context where users can save, manage and share its own resources by also managing access permissions to other groups of users.

MapStore is not only a product but also a WebGIS framework. As a standard geoportal product, it is a web-based product that allows to provide a powerful and interactive geospatial WebGIS, it provides a direct and real-time access to geospatial data warehouses and it supports the most common standards

formats available for geospatial data. MapStore also provides advanced spatial analysis capabilities that can be used to build WebGIS solutions through a powerful, dynamic and open geospatial application. Since MapStore is also a framework, you can use it to build your own WebGIS applications by using its plugins and modules.

Last but not the least, MapStore is map agnostic and ensures the greatest flexibility: its abstraction tier allows to work with different web mapping libraries. The mapping engines currently supported by MapStore are OpenLayers (used by default for desktops), LeafletJS (used by default for mobile devices) and Cesium 3D viewer.

MapStore has been designed from the beginning to provide a coherent and comprehensive experience across different devices types.

MapStore is based on OpenLayers, Leaflet and ReactJS, and is licensed under the Simplified BSD license.

### Supported Browsers

The browsers supported by MapStore are Google Chrome, Microsoft Edge, Mozilla Firefox and Safari. Ensure to have the latest version installed.

## Quick Start

You can either choose to download a standalone binary package or a WAR file to quickly start playing with MapStore. See the Quick Start documentation for more details.

### Documentation

- Users Guide
- Developers Guide

# Home Page

In order to get started, let's take a look at the portal interface and get an idea of how to navigate around it. First of all it's necessary to specify that the user can take advantage of different tools and sections according to his authentication in MapStore. In particular, a user can access the MapStore application by:

- Anonymous user
- Normal user
- Administrator user

#### Anonymous user

Accessing MapStore as anonymous user, the Homepage shows up as in the figure below:

, · · · · · · · · · · · · · · · · · · ·	A Martin Martin		
64	MapStore		
			-
	Modern webmapping with OpenL Visit the documents

A STATEMENT	The second se		

The anonymous user is allowed to:

. Navigate through the Featured and Contents sections

• Set the application language, with the Language switcher:

- Login (more information about Login can be found in Managing Users and Groups section)
- Perform a search for resources, through the Search bar:

• Open the **Advanced Filters**, through the **▼** button, to select one or more Contexts from the dropdown menu and find all maps created from them

	Ma	apStore	Lartes & communication	
		with OpenLayers, Leaflet ar he documentation page	nd ReactJS.	
	search		Q 🔻	
	Advanced search filters		<b>▼</b> ×	
and a line	Context		arency	
	a Select		parency insid	de a 3D

- Share a resource
- Take a look at map Details when available
- Open resources and navigate inside them according to their Permissions

### Normal user

With a login as normal user, the Homepage displays as below:

The normal user, in addition to what the anonymous user can do, is allowed to:

Create new resources like Map, Dashboard and GeoStory:

2

• View, edit and remove resources according to their Permissions

### Administrator user

Once logged in as Administrator, the Homepage it's like the following:

The admin can see and edit everything. In particular, in addition to what normal user can do, an administrator can also:

- Access the Manager button and Manage Accounts and Manage Contexts
- Manage the resources by including  $\checkmark$  or excluding  $\checkmark$  them from *Featured* section
- View, edit and remove any resource

# Managing Users and Groups

Accessing MapStore as anonymous user the **Login** button in Homepage is blue . With a click on it, the following window appears:

Login	×
Username	
Username	
Password	
Password	

Once the login is made, the same button displays in green 2 and a click on it opens a list of options:

Through these options it is possible to:

• Get the following **Account info**: *Name*, *Role*, *E-mail*, *Company*, *Notes* and *Groups* (in order to understand how these info are set see the Managing Users section)

User Details	>
Name	admin
Role	Admin
E-mail:	info@geo-solutions.it
Company	GeoSolutions
Notes	note
	Close

#### Change Password

Change Password	×
New Password	
New Password	
Retype Password	
Retype Password	
	Change Password Close

#### • Logout

Once logged as Admin, become possible to manage users and groups and the **Manage Accounts** option appears in Homepage:

Selecting Manage Accounts options, the Account Manager opens:

In this page it is possible to switch between Manage Users or Manage Groups sections:

## Managing Users

Users Acolapic A alat admir Groupe 0 10 0 10 0 0 \* alpa Rise USER alerbundi allyoucanmap Auto Groups USER Energiese ---Groups analytics Groups Goups marytra 0 0 0 **1 8** 10 0

Switching to Users Manager, the page displayed is the following:

In this page the Admin can:

• Perform a search among the existing users

Both the **New User** and the **Edit user** buttons, open the *User* editor window that is composed of three sections:

- User ID
- Other information
- Group membership

### User ID

As soon as the New User window opens, the User ID section is displayed:

New User	2
: 0	102
Jsername *	
Password * 0	
Retype Password *	

required

In this section the Admin is allowed to:

- Set the Username
- Set the Password
- Select the User role (Normal user or Admin)
- Choose if an user is *Enabled* or not. Enabled users will have a green status icon under their profile, otherwise disabled users will have a red status and will not be able to log in.

User-1	User-1
Role Groups: USER Group-1 everyone	Role Groups: USER Group-1 everyone
status V	status
A Warning	
<i>Username</i> and <i>Password</i> are the only mandatory fields. The characters.	e password must contain at least 6

## Other information

Switching to Other information section, it display the following:

New User		×
:	0	
email		
company		
notes		
	Cr	eate Close

Here the Admin can set:

- Email
- Company
- Notes

## Group membership

Through the last section of the window it is possible to manage the groups in which the user belongs to:

#### Note

The *everyone* group, set by default, it is impossible to remove since it must be attributed to all users.

# Managing Groups

		Search Groups	9	
L*Manage Users	Groups			
👷 Manage Groups	<b>≌</b> New Group			
	collaborators	earthi	EMSA Star Services	Eumetsat
	collaborators	earthi	EMSA Star Services	Eume

				geoservi
	status	status	status	status
	<ul> <li>✓ ⊗</li> </ul>	✓ ⊗	<ul> <li>✓ ⊗</li> </ul>	0

The Groups Manager section displays like the following:

Similar to what happens for the Users Manager, in this page the Admin can:

- Search Groups...

   Create a new group with the New Group button

   Image: Create a new group with the New Group

   Create a new group with the New Group button

   Create a new group with the New Group button

   Create a new group with the New Group button

   Create a new group with the New Group button

   Create a new group one, through the Edit group

   Edit or remove an existing one, through the Edit group

   Delete

   group

   Deters

   Description:

   Testers group

   status

   O
- Perform a search among the existing groups

Both the **New Group** and the **Edit group** suttons, open the *Group editor* window that is composed of two sections:

- Group ID
- Members manager
- >Attributes

## Group ID

As soon as the New Group window opens, the Group ID section is displayed:

	^
*	
	*

Fields marked with asterisk (\*) are required

In this section the Admin is allowed to:

- Set the Group Name
- Set the group Description

### Members manager

Through the *Members manager* section it is possible to choose which users are part of the group:

Tester		×		
	*	E		
Members:				
No u	sers for this g	roup		
Add Member:				
Select Member 🝷				
Create Close				
	_	_		

### Attributes

On the *Attributes* tab the admin can associate some attributes to user groups. By default MapStore allows to enter a "notes" attribute for each group. The attributes list can be configured by editing the plugin configuration in localConfig.json.

# Managing Contexts

In MapStore the **Application Context Manager** is an administrative tool designed to build and configure MapStore's viewers: the administrator is able to configure a custom MapStore viewer by choosing:

- The name of the context (the viewer will have its own specific URL)
- The default map configuration and map contents (like layers, backgrounds, catalogs, CRSs etc)
- The set of plugins available for the viewer

The Admin can access the Application Context Manager through the

A MANAGE CONTEXTS button available in the Manager option menu  $\equiv$  in Homepage.

In this page the administrator can:

· Perform a search among the existing contexts

In each context's card the administrator can:

• Sharing the context through the Share button

# **Application Context**

General Settings

In order to create a context, the *Admin* can click on the **New Context** button New Context in the Contexts page and he will be addressed directly to a wizard. The wizard is composed by the following four steps:

3 Configure Plugins

You can move through the steps of the wizard with the dedicated buttons located at the bottom right of the page.

2 Configure Map

Closed the context wizard through the Close button Close

## General Settings

This first step allows to configure the **Name** and the **Window title** of the new context.

## Configure Map

To create the context viewer, the map configuration (like the one described here opens so that the admin can set the initial state of the context map.

In particular the admin can configure the context map using the following MapStore tools:

- Catalog, present in *Burger Menu*, to configure the supported remote services (like CSW, TMS, WMS and WMTS) and add layers to the map.
- Import, present in *Burger Menu*, to import map files and import vector file.
- Annotations, present in *Burger Menu* button, to add annotations to the map.
- Table of Contents, through the solution where the admin can use all the available functionalities to manage context layers.
- Background Selector, at the bottom left of the viewer, allows the user to add, manage and remove map backgrounds
- CRS Selector, through the 
  button at the bottom right of the Footer, to switch the Coordinate Reference System of the map
- The Navigation Toolbar, at the bottom right of the viewer, is useful to the admin to explore the map.

An example of a context viewer with a new background and a layer, added to the map, can be the following:

## Configure Plugins

This wizard step allows to select the extensions that will be available in the context viewer: the user of a context will use only the plugins enabled by the administrator. Within this wizard step, all the available plugins in MapStore are present in the left side list ready to be selected for the context. The right side list contains the list of plugins selected by the administrator for the context.

Through the central vertical bar the administrator can select the plugins to include in the context viewer by moving them from the **Available Plugins** list to the **Enabled Plugins** list.

vaila	ble Plugins	$\odot$	Enabled Plugins	
ilter (	olugins by name	Ŧ	Filter plugins by name	7
0	About Tool that shows the About window	Î	Map plugin name: Map	× 0

Final Annotations Tool to draw annotations on map			
Background Selector Allows to select map background			

#### Add extensions to MapStore

The MapStore administrator can also install a custom plugin by using the **Add extension to MapStore** button (•), at the top right of the *Available Plugins* list.

Here the admin, in order to upload the plugin's package, can drag and drop it inside the import screen or select it from the folders of the local machine through the Select Files... button.

#### Through the **Add** button Add the plugin is inserted in the Available Plugins list.

Availa	ble Plugins	$\odot$	Enabled Plugins	
Filter	olugins by name	<b>T</b>	Filter plugins by name	<b>T</b>
₹	QueryPanel plugin name: QueryPanel	<b>^</b>	Map plugin name: Map	× 0
	<b>Redo</b> plugin name: Redo			
*	SampleExtension plugin name: SampleExtension	<b>.</b>		

A plugin so installed can be included in the context viewer by moving it in the *Enabled Plugins* list or uninstalled through the **Delete** button  $\overline{m}$ .

Available Plugir	IS	$\odot$	Enable	ed Plugins		
Filter plugins by r	name	<b>T</b>	Filter	plugins by name		
QueryPar	nel Ne: OueryPanel	<b>A</b>	Uľ	<b>Map</b> plugin name: Map		× 0
Redo plugin nam	ie: Redo		*	SampleExtension plugin name: SampleExtension	± 8	0
Save Allows to s	ave the changes to the map on the server					

#### Optional tools for enabled plugins

In the *Enabled Plugins* list, the following buttons are displayed for each extension:

vailable Plugins	Enabled Plugins	
Filter plugins by name	Filter plugins by name_	7
Search Bar Textual search tool (GeoCoder)	Map plugin name: Map	0
Settings Allows to edit some settings for the map (language, default in.	Zoom In           Button that increase zoom level of the map	0
Version     Shows the version of MapStore in map settings tool	- Zoom Out Button that decrease zoom level of the map	0

• The **Enable selection of current plugin for user** button 2 allows the admin to configure which extensions will be present in the Extension Library and not activated by default.

Once a plugin has been included in a context, it is active by default and available inside the viewer. The administrator can click on **Enable loading this plugin on startup** button to make that plugin not active by default: clicking on this button the plugin will not be available in the context viewer until explicitly activated by the end user through the *Extension Library*.

• The **Edit Plugin Configuration** button  $\checkmark$  allows the admin to interact with a text area to specify the plugin configuration and to override the default one.

• The **Open plugin configuration documentation** button **?** opens the **Plugins Documentation** in another page.

#### How to update extensions

Extension can be updated using two steps:

- Old extension removal.
- Uploading and installation of the new version of extension.

As previously stated, extension can be removed on "Configure Plugins" step of wizard using **Delete** button  $\overline{m}$ .

Available Plugins	O Enabled Plugins	
Filter plugins by name	Filter plugins by name	<u>Ţ</u>
QueryPanel           plugin name: OueryPanel	Map plugin name: Map	× 0
Redo plugin name: Redo	SampleExtension plugin name: SampleExtension	2 🔧 🛛 🗑
Allows to save the changes to the map on the server		

At this point extension will be removed from application completely. Save context after extension removal only if you want to be sure that extension will not be activated for the context if it's reinstalled at some point.

Do not save context and upload new version of extension right away after old version removal. Context don't need to be saved after new version installation.

With all stated above, complete workflow is:

- Open context editing and jump to the "Configure Plugins" step of the wizard.
- Delete old version of extension using **Delete** button  $\ensuremath{\overline{17}}$  .
- Upload and install new version of extension using the Add extension to
   MapStore button
- Do not save context, close wizard.

Existing configuration of extension (default or customized) will be preserved for all the contexts using extension.

## Configure Theme

The last wizard steps allows to configure the theme to use for a context. A dropdown allows to select one of the available themes (see the Styling and Theming section of the online documentation to know how to create and include additional themes to MapStore). By default in MapStore a **default** and a **dark** themes are available.

	Configure Th	eme	
	Choose a theme		
	Select	•	
	Custom Variables 🔞 clear all		
	Main Text Color 🛛	C	
	Main Background Color 🛛 🖉	P C	
	Primary Text Color 🛛 🥹	/ C	
	Primary Color 🔞	C	
	Secondary Text Color 🛛 🔞	/ C	
	Secondary Color 🛛 !	1 C	
	Make sure to not use a secondary color too sir and obviously the primary text color with its cr for the other couples of colors: main, seconda	punterpart (the same applies	
			Attiva Passa a li
1 General Settings	Configure Map	Configure Plugins	

#### **Default Theme**

The **default** theme is always available for a context and it is the MapStore default one. This theme is automatically applied to the context if the *Configure Theme* wizard step is skipped during the context creation or when the theme selection drop-down is cleared. An example of a default context can be the following:

#### Dark Theme

MapStore also provides by default an additional theme, the dark one, that can be selected from the drop-down menu to be used as an alternative theme for application contexts.

#### Configure Theme

Choose a theme		
Select		
Dark		
Main Text Color 🛛	1	С
Main Background Color 🛛 🔞	14	С
Primary Text Color 🔞	1	С
Primary Color 🛛	1	С
Secondary Text Color 🔞	1	С
Secondary Color 🛛 !	1	С

Make sure to not use a secondary color too similar with the primary one and obviously the primary text color with its counterpart (the same applies for the other couples of colors: main, secondary)

An example of the **dark** theme applied to a context is the following one:

#### **Custom Theme**

After selecting a theme from the drop-down, it is also possible to customize it from UI by enabling **Custom Variables**.

6	
Configu	re Theme
Choose a theme	
Select	-
Custom Variables 🕜 clear all	
Main Text Color 🛛 🎯	
Main Background Color 🛛	/
Primary Text Color 🛛 🥹	/
Primary Color 🔞	1
Secondary Text Color 🛛	× 0
Secondary Color 😧 !	/
Make sure to not use a secondary co	lor too similar with the primary one

and obviously the primary text color with its counterpart (the same applies for the other couples of colors: main, secondary)

Once **Custom Variables** is enabled, the context editor can modify main, primary and secondary colors for both backgrounds and texts (an helper clarifies the UI elements involved for each field in the form). Clicking on the *Change Color* button *involver* a color picker is displayed to allow the selection of the desire color, as follows:

	×			
	Configura il tema	I		
	Scegli un tema

	Colore Secondario 🛛 !	r C		
	Assicurati di non utilizzare un colore secondario tropp primario e ovviamente il colore primario del resto con stesso vale per le altre copple di colori: principale, sec	o simile a quello la sua controparte (lo		
				Attiva
				Passa a
1 Impostazioni Generali	2 Configura mappa		Configura plugin ————	

The colors that can be customized are the following ones:

- Main Text Color to choose the color used in panel or dialog texts
- Main Background Color to choose the color used in panel or dialog backgrounds
- Primary Text Color to choose the color used for icons inside toolbar, header and button texts
- **Primary Color** to choose the color used for icons inside toolbar, header and button backgrounds
- Secondary Text Color to choose the color used as button text when a button is active or selected
- Secondary Color to choose the color used as button background when a button is active or selected

#### A Warning

To ensure a good and well readable color contrast between each UI component, make sure to not use a secondary color too similar to the primary one and obviously the primary text color with its counterpart (the same applies for the other couples of colors: main, secondary).

An example of a custom context can be the following:

# **Extension Library**

The *fortier the side Toolbar, provide to the user the list of extensions ready to be activated for the viewer: that list of available extensions for the user has been defined by the the administrator during the Application Context creation.* 

The User Extensions panel opens allows the user to choose which extension to add to the viewer through the **Add Extension** button  $\checkmark$ , as follows:

#### Note

The User Extensions is enabled by the admin in the Application Context wizard.

# Map Catalog

The **Map Catalog** is an extension that can be included in the step #3 of the application context wizard to allow the end user to browse the existing MapStore maps directly inside the viewer itself. The i button, present in the Side Toolbar, provides to the user the list of the MapStore maps that are also available in Homepage.

The *Map Catalog* panel allows the user to select a map and loaded it in the same browser page, as follows:

#### Note

Selecting a map card in the Map Catalog list, the map currently in use will be replaced. In addition, if the selected map has been created in a context, also the viewer will be replaced with the one of the related map context.

For each map in the Map Catalog list the following buttons are displayed:

uii	Map Catalog	×
Search maps		<b>T</b>
	NaturalEarth CloudSDI Owner: Gnafu (second try as the first one gives an error)	<b>i x</b> S
	OSM Planet from Maps @ GeoSolutions - Domain Shardi	<b>†</b> < 6

- The **Delete** button  $\overline{1}$  allows the user to remove the map
- The Edit Properties button 🔌 allows the user to Edit Properties of the map

The Share button 🕑 allows the user to Share the map

# Map Templates

This extension allows to browse **Map Templates** in a MapStore's viewer. Supported Map Templates formats in MapStore are WMC and MapStore's native JSON. The Mi button, present in the Side Toolbar, provides to the user the list of the available templates.

For each template in the *Map Templates* list the following buttons are displayed:

i	Map Templates	×
Filter map te	emplates	₹
	Meteorite Landing MapStore JSON	≠ + ☆
UŶ	NY Roads MapStore JSON	<b>≓ +</b> ☆

• The **Replace** button allows the user to entirely replace the current map with the one defined in the template, as follows:

• The Add Template button + allows the user to add the map template contents (layers) to current map without replacing it (by default a new group is created in that case in TOC, on top of the other ones, to contains layers coming from the template to better identify them), as follows:

• The **Add to favorites** button  $\Rightarrow$  allows the user to add the template to favorites on top of the list

## Enabling the Map templates in a context

The *Map templates* extension is enabled by the admin in the Application Context wizard. In particular, this is possible in the third step of the wizard and after the extension is added to the *Enabled Plugins* list.

As soon as the **Configure templates** button **ii** is selected the *Configure templates* modal window opens, it allows the admin to manage the map templates.

Configure Templates		t ×
Available Templates	1	ව Enabled Templates
Filter templates by name		Filter templates by name
Meteorite Landing MapStore JSON	N T	- >>
MapStore JSON	N T	× ×
US states WMC format	N Î	Add templates to configuration from list of available templates
Velo WMC	<b>N</b>	

Through the *Configure Template* tool, the administrator can browse existing templates in MapStore and enable them for the context simply by moving the desired ones from the *Available Templates* list to the *Enabled Templates* list: this is possible with the central bar, as follows:

vailable T	emplates		$\odot$		Enabled Tem	nplates		
Filter templa	ates by name		Ŧ		Filter template	es by name		7
TŶ	MapStore Exported 2 variant 2	Ø	Ŵ		See. St.	Meteorite Landing MapStore JSON	P	Ŵ
TŶ	Velo WMC	•	ŵ	» > < <		NY Roads MapStore JSON	•	Ŵ
TŶ	cadastre template	A	Ŵ			US states WMC format	•	Ŵ
ΠŶ	cccccc	•	Ŵ					

### Uploading the template

It is possible for the administrator to create new Map Templates in MapStore by uploading new template files. In order to upload a new template the admin can select the **Upload new template** button () to open the **Upload new template** window:

Upload Map Template		×
Template		
	file (exp	r click to select a map template ported JSON MapStore maps or WMC files are supported)
Thumbnail	1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1	or click to import an image 300px X 180px, max 500kb)
Name	Туре	a name
Description	Туре	a description
Permissions Groups		
No rules		
Add a rule		
Select a group		can view 🔹 🕂

Here the admin, in order to import a template file, can drag and drop it inside the import area or simply click on that area to select it from the folders of the local machine.

Close Save

The admin can also add **Thumbnail**, **Name**, **Description** and **Groups permissions** as describe here

### Customize the template

The admin can also delete or modify an existing template through the buttons that are available on the left side of each templates item inside the *Configure templates* UI.

Configure Templates					‡ ×
Available Templates	$\odot$	Enabled Tem	iplates		
Filter templates by name	Ŧ	Filter template	es by name		Ŧ
Dimensions a widgets sample template to use for test	<b>1</b>	A Star	Meteorite Landing MapStore JSON	•	Ŵ
Cadastre Rennes W/MC template	>>	ПÅ	NY Roads MapStore JSON	N	Ŵ

In particular, the admin can:

- Modify the template using the Edit properties that opens by clicking on the Edit properties button
- Delete the template through the **Delete** button  $\overline{m}$

# **Resource Properties**

In order to customize the properties of a resource, the Admin or a normal user with permission can access the *Edit properties* window from the **Edit properties** button in Homepage or from the **Save** and the **Save as** buttons inside the resource viewer.

Edit properties	×
Thumbnail	
	Drop or click to import an image (best 300px X 180px, max 500kb)
Name	Type a name
Description	Type a description
Permissions Groups	
No rules	
Add a rule	
Select a group	▼ can view ▼ +

Close	Save

Through the *Edit properties* window the user can perform the following operations:

- Add a *Thumbnail*
- Add a Name and a Description
- Add a Permission rule

Warning

The name of a resource is the only mandatory field. Note that is not allowed to choose a name that has already been assigned to another resource.

## Thumbnail

It is possible to add an image as thumbnail dropping it or clicking inside the following box:

Thumbnail

Drop or click to import an image (best 300px X 180px, max 500kb)

#### Warning

The image to be added must not be larger than 500 kb and its best dimensions are 300x180 px. The supported formats are jpg (or jpeg) and png.

### Permission rules

In the *Add a rule*... section you can set one ore more permission rules in order to allow a group to access the resource. In particular it is possible to choose between a particular group of authenticated users or the *everyone* group that includes all authenticated users but also anonymous users (more information about different user types can be found in Homepage section). Moreover it is possible to choose between two different ways with which the selected group can approach the resource:

- View the map and save a copy
- Edit the map and re-save it

In order to add a rule, the user can select the group and set permissions inside the *Add a rule*... section. Once the rule is set, with the **Add** button **+** it is possible to add it to the *Permissions Groups* list.

For example, a resource that can be seen by *everyone*, should have a rule like the following:

Once a rule is set, the user can always remove it through the **Remove** button  $\times$ .

How to manage users and groups is a topic present in the Managing Users and Managing Groups sections.

### Details

Only for resources of type map, it is possible to add details to the map. This is useful to associate some information to the map or an overview description of its content. In this case the *Edit properties* window is the following:

Edit Map Properties	×
Thumbnail	Drop or click to import an image
	(best 300px X 180px, max 500kb)
Name	Му Мар
Description	My Map Description
Add New Details	4
Permissions Groups	
No rules	
Add a rule	
Select a group	
	Close Save

With a click on the **Add new details** button 🔌 it opens a panel where the user can write the details of the map.

Details Shee	t - My map																		
Font •	Normal	•	В	Ι	<u>U</u>	<del>S</del>	{}	Ξ	Ξ	-	P	°== °	Ξ	÷	Ø	i H	٢	°∑	

The text can be edited and some links and images can be added through the Text Editor Toolbar. Once the editing is done, the map details can be saved with the **Save** button Save and other buttons appear on the *Edit properties* panel.

### Edit properties

	A
Thumbnail	
	Drop or click to import an image (best 300 px X 180 px, max 500 kb)
Name	My map
Description	My map description
Details sheet	💋 🔌 🖸 🖈 🗑
Groups permissions	
No rules	
Add a rule	
Select a group	- can view - +
	Close Save

×

Here, the user is allowed to:

- Show the details preview 💋
- Edit the details 🔌
- Enable the **Show as modal**  $\[ \] button, to show the details on a modal when$ the user clicks on ABOUT THIS MAP button, which is listed in the SideToolbar options

#### Note

If the **Show as modal** button is not activated once the user opens the *About this map* button, the details are displayed on a panel.

Warning

The About this map button is visible in the Side Toolbar only when the details are present on the map.

- Enable the **Show at startup** subtractive, as soon as the user opens the map, the details panel is visualized.
- Delete the details sheet mathematical m

Once the details are saved, the **Show details** button appears also on the map card in Homepage

#### Through this, it is possible to open the details panel also from the home page.

Details Sheet - My map

#### My map destails

This map contains several layers:

#### Observatories:

This is a list of astronomical observatories ordered by name, along with initial dates of operation (where an accurate date is available) and loca includes a final year of operation for many observatories that are no longer in operation. While other sciences, such as volcanology and metec facilities called observatories for research and observations, this list is limited to observatories that are used to observe celestial objects.

# Sharing Resources

MapStore provides the possibility to share resources (*maps*, *dashboards* and *geostories*) through two different ways:

• Directly from the MapStore Homepage by clicking on the Share button present in the toolbar of each resource card

• Inside the resource by selecting the < option from the Side Toolbar

From the Share panel the user is allowed to share a resource in different ways:

- $\boldsymbol{\cdot}$  With a **direct link**
- Through a social network
- With embedded code or APIs (only available for maps)

### Link

As soon as the Share panel opens, the Link section is the one visible by default:

Share		>	<
Link	Social	Embed	
Via a di	rect link	£	
https://	/dev.mapstor	e2.geo-solutions.it/mapstore/#/viewer/openlayers/10358	
Advan	ced option	s	

Here, the user can copy the resource **URL link** or share it through the **QR code**.

## Social

The **Social** section allows the user to share the resource on the most common social networks like **Facebook**, **Twitter** and **LinkedIn** simply by clicking on the social icon.

## Embed

The **Embed** section provides to the user the needed snippets, **embedded code** or the **MS APIs** (only available for *maps*) to embed MapStore in a third party web page.

Share	×
Link Social	Embed
Via the embed	led code 🔊

Advanced opti	ons 🔲

In addition, MapStore provides options to customize a bit the embedded code:

• The user can configure **height** and **width** of the embedded resource by choosing Small (600x500), Medium (800x600), Large (1000x800) and Custom (it is possible to choose the desired size).

Advanced optic	ns	

• For dashboards, the user can show the connections between widgets on the embedded dashboard by enabling the **Show connections** 

## Advanced options

Some **Advanced options** are available for maps and geostories inside the **Share** tool.

### Advanced options for sharing maps

In case of maps, enabling the **Advanced options** in the *Share tool* the user can include the following to the share URL:

Share X
Link Social Embed
Via a direct link
https://dev.mapstore2.geo-solutions.it/mapstore/#/viewer/openlayers/10358
Advanced options
<ul> <li>Add bounding box param to sharing link</li> <li>Add center and zoom to sharing link</li> </ul>

- The **bounding box** parameter to share the current viewport of the map visualized by the user
- The desired center and zoom of the map by enabling the Add center and zoom

Share X
Link Social Embed
Via a direct link
https://dev.mapstore2.geo-solutions.it/mapstore/#/viewer/openlayers/10358?ce
Add center and zoom to sharing link Coordinate ①

Zoom 🔁 5 Add marker on loaded map

The related available options allow the user to:

• Center the shared map to specific coordinates by typing them in two different formats (*Decimal* or *Aeronautical* that can be chosen through the

button) or by clicking on the map to set automatically the coordinate fields.

- Share the map at a specific Zoom level (Min:1 and Max:35)
- Add marker on loaded map to show the center point in the shared map

Advanced options for sharing 3D maps

Once the **3D** Navigation is active on map, the user can include the following to the share URL by enabling the **Advanced options** in the *Share tool*:

• The desired center and zoom of the map by enabling the **Add center and** zoom to sharing link

Share X

-90

The related available options allow the user to:

• Center the shared map to specific coordinates by typing them in two different formats (*Decimal* or *Aeronautical* that can be chosen through the

button) or by clicking on the map to set automatically the coordinate fields.

• Share the map at a specific **Zoom level** (Min:1 and Max:35), **Heading** (Min:0° and Max:360°), **Roll** (Min:-90° and Max:90°) and **Pitch** (Min:-90° and Max:90°)

### Advanced options for sharing GeoStories

In case of GeoStories, enabling the **Advanced options** in the *Share tool* the user can include the following to the share URL:

Share X
Link Social
Via a direct link
https://dev.mapstore2.geo-solutions.it/mapstore/#/geostory/shared/115
Advanced options
<ul> <li>Link to MapStore home</li> <li>Include scroll position</li> </ul>

• The **Home button** to allow the possibility to bring the user to the MapStore Home Page if needed: that button will be automatically included in view mode inside the story toolbar just beside the navigation bar.

• The **scroll position** allows to share the URL of the current section of the story visualized by the user

# Exploring Maps

In cartography, a map is any two-dimensional graphic representation of the spatial relationships of the whole or a part of the earth. In digital cartography as in MapStore, a map consists in overlaying various layers of geographic data and their styles in data frames, and it contains various map elements such as a legend and a scale bar.

In order to create a map, the user can click on the **New Map** button **i** in Homepage and will be addressed directly to the map viewer (by default only Administrators and Normal Users can create a new map, as explained before in Homepage section):

Once a map is created and saved, it will be available in Homepage content section.

## MapStore WebGIS Portal Interface

The Mapstore WebGIS Portal interface is composed by the following main blocks:

In particular:

- The Table of Contents (TOC) shows the layers and the layers groups on the map and allows to remove or edit them, and add some new ones
- The MapStore Toolbars includes the Search Bar and the Side Toolbar, an important list of options that contains several functions and information
- The Navigation Toolbar that is mainly a navigation panel
- The Background Selector allows to add, remove or edit map's background
- The Footer includes the CRS selector, the coordinates, the scale and the credits of the layer
- The Data Frame is the space where the layers are displayed

# Table of Contents

The Table of Contents, briefly TOC from now on, is a space where all the layers and the layers groups are listed. Through this panel it is also possible to carry out the following operations:

- Add and remove layers and groups
- Perform a search between layers
- Change the position (and consequently the display order in map) of layers and groups
- · Set some display options directly from the panel
- Manage layers and groups and query layers through the toolbar actions

## Add and remove layers and groups

The user can access the TOC with the **Layers** button of the map viewer. For example, in a new map, the following panel appears:

The Add Layer button 🥩 opens the Catalog, a panel where it is possible to choose the desired layer and add it to the map with the Add to Map button +:

<b></b>	Catalog		×
Service			
GeoSolutions (	GeoServer CSW	x 🔻	× +
text to search.			
Search			
	DE_USNG_UTM18		+
Preview Not Avaliable	mapstore DE_USNG_UTM18		
	Meteorite_Landings_from_NASA_Open_Data_Portal		+
Preview Not Avaliable	mapstore Meteorite_Landings_from_NASA_Open_Data_Portal		
	Types		+
Preview Not Avaliable	A simple layer with all the existing supported attriute types		
10.173	mapstore.Types		
Preview Not	states		+
Avaliable	mapstore states		

Once the layer is added to the map, the result should be like the following:

In order to add a new group, clicking on the **Add Group** button rightarrow the following window opens:

Cancel	Add
	Cancel

Once the name of the group is typed, with the	Add	button the new group is
added to the TOC.		

In order to add a new layer to a specific group, it is possible to select that group and click on **Add layer to selected group** 

In order to add a subgroup inside a specific group selected, the user can click on the **Add sub group to the selected group** button 📑 (maximum 4 subgroup levels are allowed):

Layers and groups can be removed selecting them and clicking on the **Remove** button present in the toolbar of each selected layer and group.

# Search for layers

With the TOC it is also possible to perform a search between the added layers. This operation can be done simply by typing the name (o part of it) of the layer in the search bar:

# Choose layers and groups position

With the drag and drop it is possible to change layers position inside the same group, but also moving them between different groups. Once the *Default* group is created, all the layers without a specific group are automatically added to this one. Changing layers position with the drag and drop, for example, it can display like the following:

Groups and sub-groups, no matter their level, can be nested inside other groups and sub-groups, or can be separated from their parent-level to create new main groups. These operation can be performed, again, with the drag and drop function.

#### Warning

The only constraints applied to the groups manager refer to the *Default* group (each layer added to the map the first time is included in that group). Drag and Drop operations are not allowed for the *Default*, but it's allowed to rename it or to nest groups or sub-groups inside it.

Layers position can also be determined through the **Selected layer settings** button available in the toolbar that appears once a layer is selected. This button opens a panel where the user can choose the destination group (or subgroup):

×		_	America sample imagery		
	۹.	•	- /		
Title

Ame	rica				
Defa	ult				
Ame	rica				
Ame	rica/North A	merica			
Euro	ре				

# Display options in panel

Directly from the TOC panel, it is possible to set different types of display options. In particular, for layers, it is possible to:

- Toggle layers visibility by switching on 💿 and off 💋 the "eye" icon to the left of the layer name
- Expand or collapse the legend by clicking on the < icon. The width and height property of the legend can be overridden via Legend options under Display tab.
- · Control the transparency in map by scrolling the opacity slider

note
When the user switch off the visibility of a layer, also the group where that layer is nested change the "eye" icon in 💉 (no matter if other visible layers are present in that group)

With groups there's the possibility to:

- Expand 📂 or collapse 📘 the list of layers or subgroups nested inside it
- Toggle groups visibility by switching on 💿 and off 💋 the "eye" icon to the left of the group name

# Toolbar options

Once a group is selected the following toolbar appears:

Through this toolbar it is possible to:

- Add layer to selected group <i : it is possible to add one or more layers to the group
- Add sub group to the selected group 📑 : it is possible to add one or more sub-groups to the selected group
- Zoom to selected layers extent 😒 : in order to zoom the map to all layers belonging to the group
- Open the **Selected group settings** where it is possible to change the group's title, the title translations and see the group name (its ID). It is also possible to add/customize the description of the group and configure the tooltips placement in the UI (more information can be found in Layer Settings section)

		8		
Title				
Def	ault			
Title t	ranslations			
	Italiano			
	English			
	Français			
	Deutsch			
=	Español			
Name	9			
Def	ault			
Descr	ription			
Toolti	p		Placement	
Title			Тор	

Once the changes have been made, it's possible to save them through the **Save** button **P**.

Selecting a layer, the toolbar is the following one:

In this case the user is allowed to:

- Zoom to selected layer extent 😒 : in order to zoom the map to the layer's extent
- Access the selected Layer Settings
- Set a Filter for that layer
- Access the Attribute Table
- Remove the selected layer
- Create Widgets for the selected layer
- Export the data of the selected layer 📀
- Open the Layer Metadata (if configured), to retrieve layer metadata from the remote catalog source.

Layer metadata

Identifier	68b88c6b-a65b-4107-b4d8-b3ae7ce9b9e4	*
Property="date"	2020-02-26T10:12:38	
Title	Pontons d'attente présents sur les canaux appartenant à la région Bretagne	
Туре	dataset	
Subject	<ul> <li>ponton d'attente</li> <li>infrastructures</li> <li>données ouvertes</li> <li>espace public : mobilier urbain</li> <li>Services d'utilité publique et services publics</li> <li>inlandWaters</li> </ul>	
Property="format"	<ul><li>ESRI Shapefile</li><li>ESRI Shapefile</li></ul>	
Droporty "modified"	2040 04 04	•

#### Note

The **Metadata Tool** is not configured by default in MapStore. A complete documentation to configure it is available as part of the TOC Plugins documentation (see *metadataOptions*). Once the **Metadata Tool** has been configured, MapStore is able to load the layer metadata from the remote CSW service and parse it to be presented to the user according to the provided plugin configuration. This functionality automatically works in case of WMS layers coming from a CSW catalog source, while for layers coming directly from a WMS catalog source the Metadata Link must be present in the WMS Layer GetCapabilities.

From the dropdown menu of the **Compare tool** it is possible to click on Swipe button so that the Swipe tool is enabled on the map for the selected layer: to activate the Swipe it is also possible to simply click on the **Compare tool** button.

From the Compare tool dropdown, it is also possible to click on Configure . Doing this a configuration modal opens for the selected Compare tool (*Swipe* or *Spy glass*) so that, in case of Swipe, the user can change the orientation of the swipe from *Vertical* to *Horizontal*.

The user can also activate the Q Spy glass from the same dropdown menu in order to switch the Compare tool in **Spy glass** mode. If the *Spy glass* is active, clicking on the Configure option, the configuration modal opens so that it is possible to change the size of the spy glass (the radius).

# Layer Settings

In this section, you will learn how to manage the layer settings in terms of general information, display mode, style and feature Info. Since a layer is added to the TOC it is possible to access its settings with the dedicated button that appears selecting a layer:

×	۵
10%	
Filter layers	Ŧ
🕙 🚺 🖬 🖬 📶 🕥	÷ -
● Default	1
$\equiv oldsymbol{O}$ States of US	<b>&lt;</b> 100 %

The layer settings panel is composed of four sections:

#### . Feature Info

# General information

By default, as soon as the user opens the layer settings panel the General information section appears:

×	States	of US		2	4		*
	E	3			No.	$\leftarrow$	-
2	0	1	*	•	PICE.		
Title						J.	
States of US					14	45-	1
Title translatio	ons					WA WA	
Italiano						OR	7 102
English							
Français						4	NV U
Deutsch						Ec	A
💳 Español						2	A
Name						Los	Agilgetes
gs:us_states							. 19
Description							2-4
							1
				Â			
Group							
Default				*			
Tooltip			Placeme	nt			
Title			Тор				

In this page it is possible to:

- Change the Title
- Set the *Title translations*, that will be switched by changing the language
- Take a look at the Name of the layer
- Edit the layer's Description
- Set the layer Group
- Configure the *Tooltip* that appears moving the cursor over the layer's item in TOC. In this case the user can decide that the *Title*, the *Description*, both or nothing will be displayed. Moreover you can set the *Placement* of the tooltip, choosing between *Top*, *Right* or *Bottom*:

Title	
Description	Тор
Title and Description	Right
No Tooltip	Bottom

Setting a tooltip that shows the Title and the Description on the Right, for example, it can be similar to the following:

-	a la	à
	A.	Xal
Ŧ		2 .
ald		DS
-		
descript		
- 100 %		
	States of US - description	States of US - My first description

# Display

Through the second section of the layer settings panel it is possible to change the display settings:

×	States	of US	2	
*	Display	1	Ŷ	
Format				
image/png			- S	
WMS Layer tile size				
256			-	
Opacity %				
100			\$	
Visibility limits			S	
Max value (exclude	d)			
Select max value			•	
Min value (included	)			
Select min value			•	
Limits type				
Scale			•	

- ✓ Transparent
- Use cache options
- Single Tile
- Enable localized style
- □ Force proxy

#### Legend

Height	
12	<b>^</b>
	12

Preview

>= 159.05 and < 77987.8</li>
 >= 77987.8 and < 121506.4</li>
 >= 121506.4 and < 177877.5</li>
 >= 177877.5 and < 248646.7</li>
 >= 248646.7 and <= 688219.1</li>

In particular, the user is allowed to:

Set the image format: choosing between png, png8, jpeg, vnd.jpeg-png, vnd.jpeg-png8 and gif

Note

The list of available format is the same of the related catalog source. Therefore, for WMS services, the updated list of formats supported by the WMS server is used.

- Set the size of layer tiles: choosing between 256 or 512
- Set the opacity value of the layer (in %)
- Enable/disable the Visibility limits to display the layer only within certain scale limits. The user is allowed to request the MinScaleDenominator and MaxScaleDenominator value present on the WMS GetCapabilities of the layer though the S button or set the Max value and the Min value and select the Limits type choosing between Scale or Resolution.
- Enable/disable the transparency for that layer
- Enable/disable the use of the layer cached tiles (if checked, the *Tiled=true* URL parameter will be added to the WMS request and to use tiles cached with GeoWebCache)
- Decide to display the image as a single tile or as multiple tiles
- Enable/disable the localized style. If enabled allows to include the MapStore's locale in each **GetMap**, **GetLegendGraphic** and **GetFeatureInfo** requests to the server, as explained in the WMS Catalog Settings
- Enable/disable the *Force proxy* layer option. If enabled, forces the application to check the source and applies proxy if needed.
- Set the layer *Legend* with custom *Width* and *Height* options. Both of these field values if greater than the default legend's size of 12, then the custom values gets applied on the legend width and height display property
- A preview of the legend is shown with the applied custom values from Legend fields above.

#### Warning

The *Format* and *Layer tile size* options are available only for the layers added from CSW and WMS catalog sources.

Cached tiles works with WMS only with standard gridsets (exponential). When MapStore uses custom scales, the tile cache can not be used. This because WMS TileGrid for OpenLayers (internal MapStore mapping library) and the TileGrid generated by GeoServer have different origins (top-left vs bottom-left). While for exponential resolutions the top left remains fixed (because there is only an integer number of tiles in the interval between top-left and bottom-left corner of the bbox, 1, 2, 4, 8 ....) with custom resolutions the number of tiles is not integer, so the coordinate of the tile of top-left may vary across scales. More details about this limitation in this issue on GitHub.

## Style

The third section, dedicated to the layer style, displays like the following:

In this case the user is allowed to:

- · Search through the available layer styles and select the desired one
- Create a new style
- Edit an existing style
- Delete an existing style

#### Note

By the default service security rules the GeoServer's REST APIs are available only for the GeoServer administrators, so a basic authentication form will appears in MapStore to enter the *Admin* credentials. Without Admin rights, the editing capabilities on styles are not available and only the list of available styles will appear to allow the user to select one of them to the layer.

Take a look at the User Integration with GeoServer section of Developer Guide in order to understand how to configure the way MapStore and GeoServer share users, groups and roles. If the users integration between GeoServer and MapStore is configured, the editing functionalities of the styles will be available according to the role of the authenticated user in MapStore in a more transparent way.

### Create a new style

It is possible to create a new style with a click on the *stage* button. At this stage the user can choose between different types of template from which the customization will start:

- CSS Cascading Style Sheet (a language used for describing the presentation of a document written in a markup language like the HTML)
- *SLD Styled Layer Descriptor* (an XML schema specified by the Open Geospatial Consortium OGC for describing the appearance of map layers)

		CSS	SLD
Solid fill	Forest fill	Base CSS	Base SLD

#### Note

The availability of the style formats depends, firstly, from the GeoServer. MapStore, by default, will add all the supported format that the server provides. To edit or create styles using the CSS format the CSS extension must be installed in GeoServer

Once the new style is chosen, with a click on the + button the following window opens:

Create new style	×
Title	
My Custom CSS	
Abstract	
Base CSS Customization	
	Save

Here the user can set the *Title* and the *Abstract* (optional), and through the **Save** button the new style will be automatically added to the styles list.

### Edit an existing style

Existing styles can be edited clicking on the </>> button. The page that opens allows the user to customize the style in the related format:

The editor is easy to approach thanks also to the following functions:

• The *sintax control* highlights any possible error with a red underline (if error are detected an icon with a red exclamation point will be shown in the top-right side of the editor)

• The *autocomplete* function suggests the possible style's properties in order to prevents syntax errors:

• The *color picker*, that can be activated through the square filled icon (**m**) near the color code, helps in choosing colors directly from the editor, showing an interface like the following:

<pre>1 @styleTitle ' 2 @styleAbstrac 3 4 * { 5 stroke #99 6 mark: symbo 7 :mark { fi 8 }</pre>			omizat	ion';		×
	FFoooc 2 Hex	255 O R G		DOG A		
Warning						
e autocomplete and the co	olor picker fund	ctions are a	ivailable	only in the C	SS editor.	

### Visual Editor Style

MapStore also allows to edit the layers style using a *Visual editor* with a most user friendly UI.Clicking on the **Visual editor** button a section opens so that the user can customize the style through with a visual style editor by adding/editing symbolizers, which can be: *Mark, Icon, Line, Fill* and *Text*. It is anyway possible to switch to the text editor mode if necessary for a more complex styling.

Once a symbolizer has been added and customized, you can:

5 C	⊙⁺	<b>Q</b> <sup>+</sup>	\$⁺	₽	Т
Enter legend label			₹	ø	Ŵ

- Add a **Scale denominator filter** (max and min scale) to visualize the style rule only within certain scale limits. This is possible by clicking the *starter* button.
- **Remove** the symbolizer by clicking the  $\overline{m}$  button.

#### Mark

The mark type allows you to add a mark to the layer: clicking on the  $\textcircled{o}^+$  button a mark panel appears:

The mark can have different Shape, Color, Stroke with different Color and Width and customizable Radius and Rotation. Take a look at the following example.

### lcon

With the icon panel, which opens by clicking on  $\mathbf{Q}^+$  button, the style editor is allowed to add an image as an icon (by specifying its *URL*) and customize the icon Opacity, Size and Rotation angle:

#### Line

The line rule is used to style linear features of the layer: clicking on the  $\uparrow$  button a panel allows the user to edit the corresponding properties.

×	State	es of US		2

Stroke width		1 px		
Line style				
Line cap		Butt	Round	Square
Line join		Bevel	Round	Miter

The editor can change the Stroke color, the Stroke width, the Line style (continuous, dashed, etc), the Line cap (Butt, Round, Square) and the Line join (Bevel, Round, Miter). An example can be the following one:

#### Fill

The Fill rule is used to style polygon features. Clicking on 🔀 button, the editor is allowed to customize the Fill color, the Outline color and the Outline width:

### Text

The Text rule is used to style features as text labels. Text labels are positioned either at points or along linear paths derived from the geometry being labelled. Clicking on the T button a specific panel opens:

The editor is allowed to type the name of the layer attribute to use for the Label and the dropdown list is filtered accordingly to show the existing attributes that are matching the entered text (the user can anyway directly select an attribute from the list). Moreover, the style editor can customize the Font Family (*DejaVu*) Sans, Serif, etc), choose the font Color, Size, Style (Normal or Italic) and Halo weight (Normal or Bold) and select the desired Halo color and Halo weight. It is also possible to choose the text Rotation and Offset (x and y). En example can be the following one

### Style Methods

Different styles methods can be used for each style rule. Clicking on the button, available on top of the panel of each symbolizer, the editor can choose one of the following depending on the rule type:

- Simple style
- Classification style
- Pattern mark style (available only for rules of type Line and Fill)
- Patter icon style (available only for rules of type Line and Fill)

#### Simple style

The Simple style is the default style described above for each symbolizer.

### **Classification style**

MapStore allows you to classify the style based on the attributes of the layer. The *Classification style* is available for *Marker, Line, Fill* and *Text* by clicking on the **:** button and choosing the **Classification style** options from the dropdown menu.

It this case the editor is allowed to choose a Color ramp and the order (with Reverse order ) of the classification intervals colors. It is obviously possible to select the layer Attribute to use for the classification along with the

classification Method (*Quantile, Equal interval, Natural breaks* and *Standard deviation*), the number of classification Intervals and the Opacity (%) of each interval range. An example of the *Classification style* for a *Fill* rule type can be the following one:

### Pattern mark style

With the *Pattern mark style* it is possible to represent *Line* or *Fill* style rules with a mark by clicking on the **button** and choosing the **Pattern mark style** options from the dropdown menu.

×	States of US	2
	← ✓	
*	•	•
		Code editor
<b>)</b> (		⊙⁺ ♥⁺ \* \\$ T
Enter legend label		<b>T</b> 💉 🗑
\$		:
Shape		
Fill color		1
Stroke color	1000	
Stroke width	- 1 px	
Radius	16 px	
Rotation	0°	
Stroke width	- 1 px	
Line style		<b>•</b>
Line cap	Butt R	ound Square
Line join	Bevel R	ound Miter

The style editor can configure a *Mark* as explained here along with the usual options available for rules of type line or fill depending on the selected symbolizer. Take a look at the following example of the *Pattern mark style* for the *Line* rule sample.

### Patter icon style

With the *Pattern icon style* it is possible to represent *Line* or *Fill* style rules with an icon by clicking on the **i** button and choosing the **Pattern icon style** options from the dropdown menu.

The style editor can configure the *lcon* as explained here along with the usual options available for rules of type line or fill depending on the selected symbolizer. Take a look at the following example of *Pattern icon style* for a *Fill* rule sample.

## Styling on the 3D navigation

Thanks to the new improvements made to the *Visual Style Editor* editor, when 3D Navigation is enabled, the editor has the ability to customize the style of **3D Tiles** and **vector layers**.

### Styling of 3D Tiles layer

With MapStore it is possible to customize the style of a 3D Tiles layer client side. The MapStore support is working in respect of the 3D Tiles Specification 1.0 and on top of the Cesium Styling capabilities. Below is an example of how the Style Editor of a 3D Tiles layer is appearing in the MapStore UI.

For the 3D Tiles styling, while with the **Code Text Editor** it is possible to leverage completely on the styling specifications:

The MapStore Visual Style Editor supports for now only a limited set of capabilities:

Customization of the Fill color

• Style Rule filtering based on the available properties dictionary defined in the tileset.json

• Possibility to customize the radius in case of point cloud features

### **Styling of Vector layer**

In 3D mode MapStore allows to customize the style of the Vector layer through the Visual Style Editor using the same styling options available in 2D mode as described in the previous chapter.

In addition the **3D model** rule type is also available. From the *Visual Style Editor*, by clicking on *to allow adding* a 3D model (based on gITF, GLB is also allowed) as an external graphic by specifying its *URL* (see also the Cesium documentation). Furthermore, it is possible to customize the 3D model Scale, Rotation and Color. Take a look at the following example.

>	<	V_INTE	RVENTI	2		<b>L</b>				
	×	0	1	<b>Q</b> Code editor						
	<b>)</b> (			⊙* <b>9</b> * ø* T						
	Enter legend label			<b>y</b>	and I			LAR	A CONTRACTOR	
	ĩ				-				The Date	F
	3D Model		http://demo.geo-	solutions.it 🗃						
	Scale		0.1			EL.		A STREET		10-0
	X axis rotation		ol 📋 🖨 °			12 - The			Mil St	T.
	Y axis rotation		0 °			1LE				
	Z axis rotation		0 °		AV			1 Parts	111	AB
	Color			1		1 stort and a	The state		1 11	

### Warning

For the Vector layer, the Visual Style Editor have some limitations:

- It's possible to apply only one type of symbolizer at the time, so if the rule editor shows multiple rule with the same filter, only the first one is used.
- For the *Line symbolizers*: the *Line cap* and *Line join* options are not available as properties in Cesium

Furthermore, for **WFS layers**, MapStore adds some additional styling options in the *Visual Style Editor* such as:

• **Bring to front** (available for Icon, Mark and 3D model symbolizers) to bring in front and so to make visible (if set to *true*) all features covered by 3D Tile

layers and the Terrain layer (for this last case when the *depth test against terrain* option is enabled in Global Settings).

×	V_IN1	FERVENTI		3							
*	0		1	\$					Y		
<b>)</b> (				Code editor			. All			團,	- And
Enter legend label				<b>y b</b>	\$	-			de la		
•											1 M
Shape					-						2
Fill color				1							ANE
Stroke color		200						TAN			
Stroke width		1	рх							1	
Radius		12	рх			CC I				10	
Rotation		0	o			- Hr			LE

Height reference f	from ground	None	Relative	Clamp			T THE	A HE		a com	
Height		Point h	eight	• :							
Leader line color						NO K					
Leader line width		0	рх					THE STATE			R

• Height reference from ground (available for Mark, Icon, 3D Model and Text symbolizers) to indicate the reference for the point height between None (to the absolute zero of the ground), Relative (to the terrain layer level) or Clamp (the feature is clamped to the Terrain, if present, or to the ground). It is also possible to finely configure the Height value of the point symbols by choosing between one of the attributes of the feature (where *Point height* indicates the intrinsic height of the feature geometry) selecting *Attribute Value* or choosing *Constant Value* that allows to set the raw value of the height.

• Leader line (available for Mark, Icon, 3D Model and Text symbolizers) to add a line to connect the point symbol with the Terrain/Ground to have a more clear reference of the effective point position when the camera orientation change. The editor can choose the **Width** of the line and the **Color** through the usual *color picker*.

• **Clamp to ground** to enable/disable the boolean property specifying whether the line or polygon features should be clamped to the ground (this option is available for Line and Fill symbolizers).

		3
•		1
		Code editor
		₽+
		<b>y b</b>
		1
	000	
3	рх	
True	False	÷
		Both
	3 True	3 px True Folse

• **Clamp to ground reference** to choose whether the drape effect, should affect 3D Tiles, Terrain or Both. This option is available for Fill symbolizers and it is only enabled when the *Clamp to ground* option is set to True

# Feature Info Form

Through the last section of the layer settings panel, it is possible to decide the information format that appears querying a layer with the Identify Tool:

In particular, the user can choose between:

- Disable Identify to disable the Identify for the layer
- Text
- HTML
- Properties
- Template

Note

Without selecting any format here, the Identify Tool will return the layers information with the format chosen in Map Settings (in the Side Toolbar). Once a user specifies the information format in layers settings, instead, that format will take precedence over the map settings only for that specific layer.

### Text

An example of layer information in text format can be:

```
Results for FeatureType 'https://gs-stable.geo-solutions.it/geoserver/geoserver:us_st
ates':
-----
the_geom = [GEOMETRY (Polygon) with 297 points]
STATE NAME = Montana
STATE_FIPS = 30
SUB_REGION = Mtn
STATE ABBR = MT
LAND_KM = 376990.894
WATER KM = 3858.589
PERSONS = 799065.0
FAMILIES = 211666.0
HOUSHOLD = 306163.0
MALE = 395769.0
FEMALE = 403296.0
WORKERS = 293243.0
DRVALONE = 250373.0
CARPOOL = 41442.0
PUBTRANS = 2050.0
EMPLOYED = 350723.0
UNEMPLOY = 26217.0
SERVICE = 123090.0
MANUAL = 43619.0
P MALE = 0.495
P_FEMALE = 0.505
SAMP POP = 150091.0
```

### HTML

An example of layer information in HTML format can be:

us\_states

fid S	STATE_NAME	STATE_FIPS	SUB_REGION	STATE_ABBR	LAND_KM	WATER_KM	PERSON
us_states.28 S	South Dakota	46	W N Cen	SD	196575.21	3169.429	696004

us\_states.28

### Properties

An example of layer information in properties format can be:

STATE\_NAME South Dakota STATE\_FIPS 46 SUB\_REGION W N Cen STATE\_ABBR SD LAND\_KM 196575.21 WATER\_KM 3169.429 **PERSONS** 696004 FAMILIES 180306 HOUSHOLD 259034 MALE 342498 FEMALE 353506 WORKERS 250825 DRVALONE 233478 CARPOOL 32610 PUBTRANS 971 EMPLOYED 321891 UNEMPLOY 13983 **SERVICE** 119594 MANUAL 41921 P\_MALE 0.492 P\_FEMALE 0.508 SAMP\_POP 162746

## Templates

In this case the user can customize the information format:

3	0 /	•
		•
	TEXT Shows feature info results as plain text	
	HTML Shows feature info results as html	
ISON	PROPERTIES Shows feature info results as properties list	
0	TEMPLATE Customize feature info results format	
Jse \$	[] to wrap the properties you need to display	
Jse \$	[] to wrap the properties you need to display	

In particular, by clicking on the 🔨 button, the following text editor appears:

Edit cu	stom format	

Normal	\$ в	I	U	Ø	Ξ	≣	$T_{x}$

1

Here it is possible to insert the text to be displayed through the Identify Tool, with the possibility to wrap the desired properties.

Let's make an example: we assume to have a layer where each record corresponds to a USA State geometry in the map. In the Attribute Table of this layer there's the STATE\_NAME field that, for each record, contains a text value with the name of the State.

If the goal is to show, performing the Identify Tool, only the State name, an option could be to insert the following text on the Template text editor:

In this case, by clicking on the map, the Identify Tool returns:

Clos

Using the \${properties.NAME\_OF\_THE\_FIELD} syntax, MapStore is able to parse the response to the Identify Tool request by matching the configured placeholder.

# Filtering Layers

When using vector layers it might be useful to work with a subset of features. About that, MapStore let the user set up a Layer Filter that acts directly on a layer with WFS available and filter its content upfront. The map will immediately update when a filter is applied.

### 🛕 Warning

The MapStore's filtering capabilities are working on top of the WFS specifications so that service must be enabled if you want to filter a layer using the tools described in this section.

## Filter types

In MapStore it is possible to apply filters on layers in three different ways:

- With the Layer Filter tool available in TOC
- With the Advanced Search tool available from the Attribute Table
- With the Quick Filter available in the Attribute Table

### Layer Filter

This filter is applicable from the **Filter layer** button in TOC's Layers Toolbar and it will persist in the following situations:

• Using other tools like the Identify tool:

• Applying another type of filter

		Amongoringo.		
STATE NAME				
STATE_NAME				
Augustantes Sacare				
Supt. meson haven.				
) oto musici salar. 23. – Calorado 24. – Kansas				
i un muse nam R Calanzas R Mansas R Mabraska				
) oto musici salar. 23. – Calorado 24. – Kansas				

• Opening the map next time (you need to Save the map from the Side Toolbar after applying a filter)

Once a *Layer filter* is set, it is possible to enable/disable it simply by clicking on the button that will appear near the layer name in TOC:

This filter is applied through the Query Panel. Once the settings are chosen, it is possible to **Apply** them. After that the user can:

- Undo 🌖 the last changes
- Reset  $\overline{\mathbf{x}}$  the filter to the initial situation
- Save 📋 the filter in order to make it persistent

## Advanced Search

This filter, applicable from **Advanced Search** button  $\overline{\gamma}$  in Attribute Table, behaves as follows:

• It can be used to apply a filter to a layer for search purposes in Attribute Table: this filter is applied in AND to the *Layer Filter* if it is already been set.

				UT_UT_UT	ат, <u>NE NE</u> 200 — К			1 + 17
				La repri		- Mangal	H Danser	
	TATE,NAME	STATE, FRS	SUB, REGION	Process STATE_ABBR	States of US	WATER, KM	PERSONS	
		and the second second		Poperse Poperse	States of US			FAMILE
Î	TATE, NAME	STATE, FIPS	SUE, REGION	Poerse STATE_ADDR	States of US LAND, KM	WATER, KM		FAMILIES
0	TATE, NAME	STATE_FIPS	SUE, REGION	TATE_ABBR	States of US LAND, KM	WATER, KM	Type survivor or expression	FAMILIE
0 8	TATE, NAME True institut film.	STATE_FIPS Type-leaf to films	SUB,REGION There lead on Rose.	Total local film	States of US LAND_KM Type number of repense of Wegg Sets	WATER, KM Test contain of boolean 900.954	Type summer or separate	FAMILIES Trees no (5424
C N N	TATE_NAME	STATE_FIPS Trans-land to Alam. 10	SUB, REGION Trans Instantions Mits WIN Cen	Property Report	States of US LAND_XM Type number of represent of 00505.501 despts.641	WATER, KM Tree content of teams 900-954 Lasti Hos	True number of expension 37(43)4 2477534	058500

 $\cdot$  It is possible to sync this filter with the map through the  $\mathbf{M}$  icon:

• It will be automatically removed/reapplied by closing/opening the Attribute Table

Also this filter is applied through the Query Panel but in this case it is not possible to Save it and make it persistent reopening the map the next time. The user is only allowed to apply it by clicking on **Search Q** or eventually **Reset** 

### **Quick Filter**

The user can perform three type of quick filters:

- Filter by **attributes**
- Filter by clicked point in the map

### Filter by viewport

### **Quick Filter by attributes**

This filter is available for each colum in the Attribute Table just below the field names and it can be also used in combination with other filter applied:

			Sector Wonkington Portland Organ Boise- Sacramento Sacramento Conforma Lan Locangeles	UT_shUL CSy UT_cm/UT Abuq	NE NE Netrosta	Moverate Minnespols viscous Loron Des Moines Jiews	Michagan Minaukee Detroit Chicago Indiana Ohio Louisville West Way Kentucky	Virginia Virginia Beact North Care
	STATE_NAME	STATE_FIPS	SUB_REGION	STATE_ABBR	LAND_KM	WATER_KM	PERSONS	FAMILIES
	Type text to filter	Type text to filter	Type text to filter	Type text to filter	Type number or expressic	Type number or expressic	Type number or expressic	Type number or
R	Colorado	08	Mtn	со	268659.501	960.364	3294394	854214
S.	Kansas	20	W N Cen	KS	211921.641	1188.865	2477574	658600
2	Nebraska	31	W N Cen	NE	199113.203	1244.957	1578385	415427
9	Utah	49	Mtn	UT	212815.546	7086.152	1722850	410862
3	Wyoming	56	Mtn	WY	251500.801	1848.149	453588	119825
	ems							

The user has the possibility to apply simple filters by attributes simply typing the filter's value in the available input fields (Date or Time pickers are available according to real attributes data types and a tooltip usually gives an information on how to fill the filter's input field). Filtering by one or more attributes, layer records in Attribute Table are automatically filtered accordingly.

If the user wants to filter by an attribute of type String, he can simply write something inside the input box and the list of records in table will be automatically filtered by matching with the input text.

		Los Angeles		Washington	
	7 🛇 🖬 🖬	dd ui		USA Popu	lation
	STATE_NAME	STATE_FIPS	SUB_REGION	STATE_ABBR	LAND_KM
	arizona	Type test to filter_	Type test to filter.	Type text to fitter.	Type number or expression
S.	Arizona	04	Mtn	AZ	294333.462

If the User wants to filter by a numeric attribute, he can type directly a number or an expression using the following operators:

- Not equal (!= or !== or <>)
- Equal or less than (<=)
- Equal or greater than (>=)
- Less than (<)
- Greater than (>)
- Equal (=== or == or =)

In order to filter a numerical filed matching the records *greater than* or *equal* to a certain threshold value, an example can be:

0	Y 🗵 🖽 🖬	ilil wi		USA Populatio	n
	STATE_NAME	PERSONS	FAMILIES	MALE	FEMALE
	Type text to filter.	>-4000000	Type number or expression	Type number or expression.	Type number or expression.
ç	Illinois	11430602	2924880	5552233	5878369
ς	Missouri	5117073	1368334	2464315	2652758
ç	North Carolina	6628629	1812051	3214286	3414343

### **Quick Filter by map interaction**

It is possible to filter records in the Attribute Table by clicking on the map or doing a selection directly in a map of multiple features. The user can activate the **Filter on the map o** button (once clicked the button turns blue) and then:

- · Click on the map over the features he wants to select
- Add multiple features to the selection by pressing Ctrl and clicking again over other features in map

• Add multiple features to the selection by pressing Ctrl + Alt and drawing a selection box in map

V       V							
			and the second se	La Habana @	Euba	<sup>δ</sup> Ω	C

The list of records in the *Attribute Table* will be automatically filtered according to such user selection and then the user can disable the geometry filter through the **Remove filter &** button.

### **Quick Filter by viewport**

From the Attribute Table the user can filter data by map viewport through the **Filter by viewport S** button. Once clicked, the toggle button turns its state to green and the list of records in the *Attribute Table* is filtered by showing only records corresponding to layer features present in the current map viewport.

The list of records in the *Attribute Table* is automatically updated when the user pan/zoom the map view. It is possible to deactivate the **Filter by viewport** by clicking again the same toggle button.

The *Quick Filter* remains active as long as the Attribute Table is open but, unlike the Advanced Search, closing the Attribute Table it will not reappear anymore if the Attribute Table is reopened in a second time.

# Query Panel

This tool is used to define advanced filters in MapStore. It includes three main sections:

- Attribute Filter
- Region of Interest
- Layer Filter

Attribute filter		
Match <b>any v</b> of the following conditions:		+
Region of interest		
Filter type	Select	•
Geometric operation	Intersects	•
Layer filter		
Target layer	Select layer	•

## Attribute filter

This filter allows to set one or more conditions referred to the Attribute Table fields.

First of all it is possible to choose if the filter will match:

- Any conditions
- All conditions
- None conditions

After that, the user can insert one or more conditions, that can also be grouped in one or more condition groups (use the Button in order to create a group). A condition can be set by selecting a value for each of the three input boxes:

- · The first input box allows to choose a layer field
- In the second input box it is possible to choose the operation to perform (selecting a text field can be =, like, ilike or isNull, selecting a numerical field, can be =, >, <, >=, <=, <> or ><)</li>
- The third input box (in case of fields of type String) provides a paginated list of available field values already present in the layer's dataset (a GeoServer WPS process is used for this). In case of numeric fields the user can simply type a value to use for the filter.

the "paginated list of available field values" above is available only if the server provides the WPS process gs:PagedUnique

A simple Attribute Filter applied for a numerical field can be, for example:

I	✓ 💾 🌖 T̄x		
Attribute filter			OR ID WY NE IA
Match <u>any</u> v of the following con	ditions:	≣ +	AZ NM OK AR TN NCA
Region of interest			México
Filter type	Select	•	
Geometric operation	Intersects	•	Colombia
Layer filter			the second se
Target layer	Select layer	•	c <sup>lm</sup>

## Region of interest

In order to set this filter the user can:

- Select the *Filter type* by choosing between **Viewport**, **Rectangle**, **Circle**, **Polygon** (selecting Rectangle, Circle or Polygon it is necessary to draw the filter's geometry on the map)
- Select the *Geometric operation* by choosing between **Intersects**, **Is contained**, **Contains**

Applying a *Circle* filter with *Intersect* operation, for example, the process could be similar to the following:

	✓ 🗄 🌖 🏹		The second secon	
Attribute filter			~~~	
Match <u>any</u> v of the following con	ditions:	□ +		1 .
land_km 🔹 >	▼ 150,000	÷	No. Contraction	24
Region of interest Filter type	Select		OR ID WY CA NV UT CA NV UT CA AZ NI	O KS MO
Geometric operation	Intersects	•		México
Layer filter				Star 1
Target layer	Select layer	•		

Once this filter is set, it is always possible to edit the coordinates and the dimensions of the drawn filter's geometry by clicking on the **Details** button x. Editing a circle, for example, it is possible to change the center coordinates (*x*, *y*) and the radius dimension (*m*):

Region of int	erest			N 7×
Filter type			Circle	
Geometric ope	eration		Intersects	•
Selection De	tails			✓ <b>T</b> . ×
	x	-104,38		
	Υ.	51.02		
	Radius(m):	1834716,96	6	

## Layer filter

This tool allows to set cross-layer filters for a layer by using another layer or even the same one.

A Warning
This filter tool requires the Query Layer plugin installed in GeoServer

In order to set up a cross-layer filter the options below are required:

- *Target layer* (between those present in the TOC)
- Operation to be chosen between Intersects, Is contained or Contains
- Optionally some Conditions (see Attribute filter)

In order to better understand this type of filter, let's make an example. We suppose that the user want to filter the Italian Regions with the Unesco Item's one:

In particular, if our goal is to take a look at the Italian Regions that contain the Unesco sites with *serial code=1*, the operations to perform can be the following:

# Attribute Table

In GIS, the Attribute Table associated to a vector layer is a table that stores tabular information related to the layer. The columns of the table are called fields and the rows are called records. Each record of the attribute table corresponds to a feature geometry of the layer. This relation allows to find records in the table (information) by selecting features on the map and viceversa.

In MapStore, through the is button in Layers Toolbar it is possible to access the Attribute table:

	🔻 🔀 🕙 dil 🖬 🖬		
	land	type	name
9	Type number or expression	Type text to filter	Type text to filter
3	0	FOREST	Mountains of The Dragon
2	2	LAKE	Lake of The Lady
2	3	DESERT	Ryukahn Desert
2	4	FOREST	Living Woods
2	5	FOREST	My Forest

5 Items (1 Selected)

Accessing this panel the user can perform the following main operations:

- Edit records through the 🔨 button
- Filter records in Attribute Table in different ways as described in the Set filter section below
- Open the Advanced Search tool through the 
   button
- Activate the filter by the current viewport, through the 🗊 button
- Activate the filtering capabilities by clicking on map, through o button
- Using the quick filter by attribute

- Download the grid data through the 📀 button
- Create Widgets through the III button
- $\cdot$  Customize the attribute table display through the  $\overline{\mathrm{Im}}$  button
- Zoom to features through the [3] button available on each record or zoom to the page max extent through the [3] button (available only if the virtual scrolling is disabled, it is enabled by default in MapStore).

#### 🛕 Warning

When GeoServer is set to strict CITE compliance for WFS (by default), the feature grid do not work correctly. This is because MapStore uses by default WFS 1.1.0 with startIndex/ maxFeatures. This is not strict compliant with WFS 1.1.0 (GeoServer supports it but the request in strict mode is invalid). To solve it un-check the CITE compliance checkbox in the "WFS" page of GeoServer "Services" configurations using the GeoServer web interface

### Manage records

The basic Web Feature Service allows querying and retrieval of features. Through Transactional Web Feature Services (WFS-T) MapStore allows creation, deletion, and updating of features.

#### Warning

By default editing functionalities are available only for MapStore *Admin* users. Other users can use these tools only if explicitly configured in the plugin configuration (see the APIs documentation for more details). In any case, the user must have editing rights on the layer to edit it (see for example the GeoServer Security Settings).

The *Edit mode* can be reached from the  $\checkmark$  button in *Attribute Table* panel, allowing to menage only the layer which the table refers to:

	▼ 🗵 ⊙ III 🖬 🖬	febrar	
	osm_id	fclass	name
•	Type text to filter	Type text to filter	Type text to filter
2	10013388	forest	
2	10013389	forest	
2	100271638	grass	
2	10032248	forest	
2	100478655	forest	
553	802 Items		

Note
When the <i>Edit mode</i> is enabled only the editing functionalities are available to the user, all other tools are deactivated.

By default, in *Edit mode*, you can see a panel like that following:

	osm_id	fclass	name
•	Type text to filter	Type text to filter	Type text to filter
$\otimes$	10013388	forest	
$\otimes$	10013389	forest	
$\mathbb{S}$	100271638	grass	
$\otimes$	10032248	forest	
$\mathbb{S}$	100478655	forest	

Through the **Quit edit mode** button  $\leftarrow$  you can stop the editing session to make the other functionalities available again.

### Create new features

Once the *Edit mode* is enabled it is possible to create a new feature by clicking on the **Add New Feature** button  $\blacksquare$ . After clicking on it the user can fill out the fields and edit the geometry of the new feature:

<b>≪ E</b>	9 ×	ui Ü -			
		osm_id	fclass		name
	9	Type text to filter	Type text to filter		Type text to filter
	1		1	-	
	2	10013388	allotments		
	8	10013389	cemetery commercial		
	2	100271638	farmland		
	8	10032248	farmyard	>	

To edit attributes MapStore provides some input fields based on the attribute type, that forces the user to insert a valid value. If the attribute is of type text, MapStore will also show a dropdown menu with the list of the existing values for that attribute to allow a quick selection.

The *Missing geometry* exclamation point in the second column of the *Attribute Table* means that the feature doesn't have a geometry yet. It's possible to add it later or draw it on the map before saving:

\$₹	E	
		land
	•	Type number or expression
	(!)	
	2	1
	2	2

In order to save the changes made until now, there's the 🕒 button, whereas to undo the changes there's the 🗵 button.

Once a new record is created, it's possible to draw a geometry for it, by clicking

on the <u>v</u> button that appears once that feature is selected. The process of drawing a new geometry is a little different depending on the layer type:

• For *Polygons* and *Multipolygons* layers, each click on the map add a new vertex (the minimum is 3). Once the vertex are set, it is possible to change the shape by creating new vertices or dragging the existing ones:

			l.		
R E	1 🗵	uť Ü-			
		osm_id	fclass	name	
	9	Type text to filter	Type text to filter	Type text to filter	
	1	100554536	forest	my forest	
	2	10013388	forest		
	8	10013389	forest		
	2	100271638	grass		
	2	10032248	forest		

• For *Lines* and *Multilines* layers the shape drawing function works more or less in the same way. The only difference is that you need at least two vertices to draw a line and not three like for polygons:

	geo	to the existing metry			
<b>B</b>		ui Ü -			
		osm_id	fclass	name	
	9	Type text to filter	Type text to filter	test	
	!		residential	test	
	2	125586813	cycleway	Skarpskyttestigen	
	2	187089515	residential	Tyssgrytestigen	
	2	22790365	residential	Jultomtestigen	
	3	242854799	residential	Entitestigen	

• For Points layers a point is drawn for each click on the map

Draw fea		ui U -			
		osm_id	name	type	
	Q	Type number or expression	Type text to filter	Type text to filter	
	1		test	monument	
	8	172,072	Novara	motorway_junctio	
	2	879,368		traffic_signals	
	$\mathbb{S}$	918,437		traffic_signals	
	8	1,313,296		level_crossing	

The user is always allowed to delete the drawn shape through the 🔀 button.

### Create new geometry with Snapping

To fine tune the vertex position while editing or creating a new feature geometry, it is possible to leverage on the Snapping functionality. Through this function it is possible to snap to other vertices of features belonging to the same layer or to others while editing a feature.

					0
\₹ 🗄	×	uĩ Ü -	fclass		
	b	osm_id		name	
	9	Type text to filter	Type text to filter	Type text to filter	
	1	34645750	forest	test	
	2	10013388	forest		
	2	10013389	forest		
	2	100271638	grass		

The tool provides the ability to tune the snapping function so that the user can:

Choose one of the visible map layers in TOC to be used for the snapping

					0
<b>№</b> E	<u> </u>	ui Ü			
		osm_id	fclass	name	
	•	Type text to filter	Type text to filter	Type text to filter	
	1	100955454	grass	test	
	2	10013388	forest		
	3	10013389	forest		
		10013389 100271638	forest grass		

- Choose where to snap the layer, enabling/disabling the Edge or/and the Vertex
- Set **Tolerance** for considering the pointer close enough to a segment or vertex for snapping
- Choose the **Loading strategy** of features to snap with by choosing one of the available options from the dropdown menu. Available options are:
- · bbox: only features in the current viewport are loaded
- all: all layer features are loaded

#### 🖍 Note

The snapping functionality is by default set to work with the same layer in editing mode. By default, the **Edge** and the **Vertex** are enabled, the **Tolerance** is set to 10 pixel and the **Loading strategy** is set to *bbox*.

### Editing and removing existing features

In order to edit an existing feature, it is necessary to switch the Attribute Table in editing mode by clicking the *Edit mode* button. If the goal is to edit the Attribute Table records, the user can simply select them and type the desired value into the input field. However, it is also possible to modify the geometry associated with a record by editing it on the map (adding or changing its vertices).

note				
-		ble		ultiple records at once by selecting the ontent onto the multiple cells, as follows:
			name	description
		9	Type text to filter	Type text to filter
		2	Capital	The Capital city
		2	prova 1	
		3	prova 2	
		2	My point	test 🖑
	1 Item			

With a click on Save changes 💾 these changes will be persistent.

In Edit mode, the user can also delete some features by selecting them in the table and clicking on the 🔳 button.

# Set filters

In the Attribute table it is possible to apply filters in four ways (as explained in the Filtering layers section):

- Advanced search
- Click on map
- Quick filter
- Filter by viewport

Those filters, once applied, can be visible on the map by enabling the button.

# Download the grid data

Form the Attribute table it is also possible to download the grid data through the 🕑 button. The following window opens:

Export Data	×
File Format	
Select	•
Spatial Reference System	
Native	•
	• Export

From this window it is possible to set:

- The File Format (GML2, Shapefile, GeoJSON, KML, CSW, GML3.1 or GML3.2)
- The Spatial Reference System (by default Native or WGS84)

With a click on the Sexport button and the browser will download the file.

### Customize Attribute table display

MapStore allows the user to customize the fields displayed in Attribute table mainly in two way:

• Ordering the records in alphabetic order (if it's a text field) or from the minimum to the maximum value and viceversa (if it's a numerical field):

	state_name	state_fips	sub_region	state_abbr	land_km	١
	Type text to filter	Type text to filter	Type text to filter	Type text to filter	Type number or expression	
٩,	Illinois	17	E N Cen	IL	143986.61

# Widgets

In MapStore it is possible to create widgets from the layers added to the map. Widgets are components such as charts, texts, tables and counters, useful to describe and visualize qualitatively and quantitatively layers data and provide the user the opportunity to analyze information more effectively.

Some widgets (in maps or in dashboards) need some WPS back-end support to work:

- The map widgets (dashboards) needs the WPS process gs:Bounds to zoom to filtered data, if connected to a table.
- For aggregate operations, chart and counter widgets need the WPS process gs:Aggregate available in GeoServer to work.

# Add a Widget

Once at least one layer is present in the map (see Catalog section for more information about adding layers), it is possible to create a widget by selecting that layer in the TOC and by clicking on the **fill** button from the Layer Toolbar or from the Attribute Table. Performing these operations the *Widget* panel appears:

$\times$	Widget	dtl
	Select the widget type	
1.1	Chart add a chart	
ılıl	auu a chan	
	Text	
	add a text area	
	Table	
	add a table	
	Counter	
	add a counter	

From here the user can choose between four different types of widget:

- Chart
- Text
- Table
- Counter

### Chart

Charts widget allow multi-selection of layer to create a widget that allows user to configure chart options for each layer. And switch between multiple charts in a widget.

Selecting a Layer or Layers, the following Chart options is presented to user:

From the chart configuration page, the user can perform the following operation

• Edit chart name 🚿

• Choose between *Bar Chart, Pie Chart* or *Line Chart*. By default, the bar chart is selected.

From the toolbar of this panel  $\leftarrow$   $\checkmark$   $\overrightarrow{}$  +  $\overrightarrow{}$   $\rightarrow$  the user is allowed to:

- Go back to the chart type selection with the < button
- Connect or disconnect if the widget to the map. When a widget is connected to the map, the information displayed in the widget are automatically filtered with the map viewport. When a widget is not linked, it otherwise shows all the elements of that level regardless of the map viewport
- Configure a filter **T** for the widget data (more information on how to configure a filter can be found in Filtering Layers section).
- Add new layers + to existing chart configuration
- Delete the current layer in and it's related chart configuration from the wizard
- Move forward • Move forward button prohibits the user from proceeding further when some chart is invalid

Just below the chart's preview, the following configurations are available:

- Define the **X Attribute** of the chart (or **Group by** for *Pie Charts*) choosing between layer fields
- Define the **Y Attribute** of the chart (or **Use** for *Pie Charts*) choosing between layer fields
- Define the aggregate **Operation** to perform for the selected attribute choosing between No Operation, COUNT, SUM, AVG, STDDEV, MIN and MAX

Note

The *No operation* option is used when the aggregation method is not needed for the chart. If *No Operation* is selected, no aggregation will be carried out for the chart and the WFS service will be used to generate the chart without using the WPS process gs:Aggregate in GeoServer.

- Enable the chart's legend by activating Display Legend
- Choose the **Color** (Blue, Red, Green, Brown or Purple) of the chart (or the **Color Ramp** for *Pie Charts*) or choose to **Customize the color**.

#### **Color customization**

For *Bar Charts* and *Pie Charts*, MapStore provides the possibility to customize the colors of the charts bars and slices. From the **Color** option dropdown menu, the user can select the *Custom* option and open the **Custom Colors Settings** modal through the statement button.

Custom Colors Settings		
Color	1	•
Classification Attribute	Select attribute 🔹	
	Close Sav	e

Inside this modal, the user is allowed to:

• Change the default **Color** of bars or slices (depending on the chart type) through the *Color Picker*. This color will be applied for all values for which a *Class Color* has not been configured.

• Select an Attribute in the dropdown list as a **Classification attribute**.

Once the attribute is chosen, new options appear in the *Custom Color Settings* panel that allow the user to:

• Enter a **Default Class Label** to be used in the legend for all values that will not be specifically classified in the following list.

🖍 Note

For both *Default Class Label* and *Class Label* '\${legendValue}' can be used as a placeholder for the Y Attribute (that can be further customized through the usual *Advanced Option*).

• Classify *Classification Attribute* values to assign a specific color in the chart along with its *Class Label* to use for the chart legend. Only values of type **String** or **Number** are currently supported.

#### **Classification Attribute of type String**

When the values of a classification attribute are of type String, the user can:

Custom Colors Setti	ngs			
Default Color				1
Classification Attribute		STATE_NAME	×	•
Default Class Label 🕜				
Class Color	Class Value	Class Label 🕜		٦
1				:

- Choose the Class Color through the Color Picker.
- Choose the value of the *Classification attribute* through the dropdown menu
   **Class Value**

Close

Save

• Enter a **Class Label** to be used in the legend for the value entered in the *Class Value* 

An example of *Bar charts* corresponding to this type of classification can be the following:

X Widget III	Galaxy Search by location name
✓ ▼ →	-Winner
Configure data	x-z
30M 💿 🔍 🕂 🖬 🖬 🔀 🕷 20M	Custom Colors Settings

Advanced Options	
	Constrained Database Constrained Database Constrain

Through the **i** button the user can add new values before through the

+ Add new entry before

button or after through

+ Add new entry after

button.

#### **Classification Attribute of type Number**

When the values of a classification attribute are numbers, the user can configure a color ramp and so:

Custom Colors Set	tings						
Default Color							1
Classification Attribute	1		PERSONS			×	•
Default Class Label 💡							
Class Color	Min Value	÷ 0	Max Value	•	Class Label 🕜		:

Close	Save
-------	------

- Choose the Class Color through the Color Picker
- Choose the Min value of the Classification attribute
- Choose the Max value of the Classification attribute
- Enter a **Class Label** to be used in the legend for the value entered in the *Class Value*

An example of Bar chart corresponding to this type of classification can be the following:

X Widget III	1 Par	Bearch by location name

### **Bar Chart Type**

If the *Classification attribute* is added to the *Bar Chart*, in the Advanced Options, the **Bar Chart Type** option is displayed.

Advanced Options		
Hide Grid:		
Bar Chart Type:	Stacked	○ Grouped

The user can customize the bars by choosing between:

• Grouped. An example can be the following:

• Stacked. An example can be the following:

### **Advanced Options**

In addition, only for *Bar Charts* and *Line Charts*, MapStore provides advanced setting capabilities through the *Advanced Options* section.

Through this section, the user is allowed to:

- Show/Hide the chart's grid in backgroung with the Hide Grid control
- Customize Y axis tick values by choosing the *Type* (between Auto, Linear, Category, Log or Date): the axis type is auto-detected by looking at data (*Auto* option is automatically managed and selected by the tool and it is usually good as default setting). The user can also choose to completely hide labels through the *Hide labels* control or customize them by adding a *Prefix* (e.g. ~), a custom *Format* (e.g. 0%: rounded percentage, '12%' or more) or a *Suffix* (e.g. Km). It is also possible to configure a *Formula* to transform tick values as needed (e.g. value + 2 or value / 100 or more)

Hide Grid:		1
Y axis		
Туре:	Ca	ategory × 🔻
Hide labels:		
Format:		
Prefix:	Format: 🕜	Suffix:
~	.0%	Km
Formula:		
value + 2		

#### Note

More information about the syntax options allowed for **Format** are available here and the allowed expression to be used as **Formula** are available here in the online documentation.

• Customize **X axis** tick values by choosing the *Type* (between Auto, Linear, Category, Log or Date): the axis type is auto-detected by looking at data (*Auto* option is automatically managed and selected by the tool and it is usually good as default setting). As per **Y axis**, the user can completely hide labels through the *Hide labels* control or tune the rendering of tick labels with options like *Never skip labels* (it forces all ticks available in the chart to be rendered instead of simplifying the provided set based on chart size) and *Label rotation* to better adapt X axis tick labels on the charts depending on the needs.

Advanced Option	IS			
Hide Grid:				
Y axis				
Туре:		Categor	× 🔻	
Hide labels:				
Format:				
Prefix:	Format: 🕜		Suffix:	
~	.0%		Km	
Formula:				
value + 2				
X axis				
Туре:		Auto		× 🔻
Hide labels:				
Never skip labels:		0		
Label rotation:				60"

#### 🛕 Warning

The tick labels available for the X axis by enabling the option **Never skip label** cannot be more than 200 in order to provide a clear chart and for performance reasons.

Set the Legend Label name

# 

Hide Grid: <b>Y axis</b>				
Type:		Categor	У	× 🔻
Hide labels:				
Format: Prefix:	Format: 🕜		Suffix:	
e.g.: ~	e.g.: .2s		Km

Туре:		Auto		× Ŧ
Hide labels:				
Never skip labels:		0		
Label rotation:				60'
Legend				
Legend Label:		land (km	1)	

In order to move forward to the next step, only **X Attribute**, **Y Attribute** and **Operation** are considered as mandatory fields.

Once the settings are done, the next step of the chart widget creation/ configuration is displayed as follows:

The user can:

- Go back to the chart option with the < button
- Configure a filter **T** for the widget data (more information on how to configure a filter can be found in Filtering Layers section)
- Add the widget to the map with the 💾 button

Just below the chart's preview, the user is allowed to set:

- The widget Title
- The widget Description

An example of chart widget could be:

The Chart toolbar, displayed in the right corner of the chart allows the user to:

÷

- Download the chart as a png through the 👩 button.
- **Zoom** the chart through the 🄍 button.
- Pan the chart through the 🔶 button.
- Zoom in the chart through the 📑 button.
- Zoom out the chart through the 📃 button.
- Autoscale to autoscale the axes to fit the plotted data automatically through the solution.
- Reset axes to return the chart to its initial state through the 🕋 button.
- **Toggle Spike Lines** to show dashed lines for X and Y values by hovering the mouse over the chart. This is useful to better see domain values on both axis in case of complex charts. It is possible to activate that option through the button.

### Text

Creating a new text widget the following window opens:

×					Widget					dt				
						VII.	÷	8						
	Insert	title	·											
No	rmal	\$	в	I	U	"	≔	≡	<u>A</u>	A	<u>T</u> *	1	B	
Inse	ert text.													

Through the toolbar it is possible to:

- Go back to the widget type selection with the < button
- Add the widget to the map with the 💾 button

Here the user can:

- Write the title of the widget
- Write the text of the widget
- Format the text through the Text Editor Toolbar

An example of text widget could be:

#### **USA States**

The United States of America is a federal republic consisting of 50 states, a federal district (*Washington, D.C.*, the capital city of the United States), five major territories, and various minor islands. The 48 contiguous states and Washington, D.C., are in North America between Canada and Mexico, while Alaska is in the far northwestern part of North America and Hawaii is an archipelago in the mid-Pacific. Territories of the United States are scattered throughout the <u>Pacific Ocean</u> and the <u>Caribbean Sea</u>.

#### Table

Adding a table widget to the map, a panel like the following opens:

\* -

## Configure table options

#### Columns

Name	Title	Description	
STATE_NAME			*
STATE_FIPS			
SUB_REGION			
STATE_ABBR			
LAND_KM			
WATER_KM			
PERSONS			
FAMILIES			
HOUSHOLD			-

The toolbar on the top of this panel is similar to the one present in Chart section. Here the user is allowed to:

• Enable/Disable the layer fields that will be displayed in the widget as columns.

• Enter a **Title** for each column to be displayed as the table header in place of the *Name* of the layer field

	1	Widget	<b>*</b>	dil					J.A.	Search by location nam	e

## Configure Widget Info

Title:	
Description:	

In this last step of the widget creation, the toolbar and the information to be inserted are similar to the ones in Chart section.

An example of table widget could be:

X

State	LAND	WATER	PERSONS	FAMILIE
Illinois	143,986.61	1,993.335	11,430,602	2,924,8
Missouri	178,445.951	2,100.115	5,117,073	1,368,3
Arizona	294,333.462	942.772	3,665,228	940,106
Oklahoma	177,877.536	3,170.998	3,145,585	855,321
North Carolina	126,177.635	10,309.652	6,628,629	1,812,0
Tennessee	105,823.567	2,311.556	4,829,958	1,334,0
Texas	688,219.07	17,337.549	17,122,020	4,377,10
New Mexico	304,472.805	586.054	1,379,559	358,259
Alabama	131,443.119	4,332.268	4,040,587	1,103,8
Mississippi	121,506.43	3,598.337	2,573,216	674,378
Georgia	148,574.888	3,934.991	6,457,339	1,707,4
District of Columbia	159.055	17.991	606,900	122,087
South Carolina	77,987.823	4,910.636	3,486,703	928,206
Arkansas	134,875.075	2,867.302	2,350,725	651,555
Louisiana	112,836.008	19,978.72	4,219,973	1,089,8
Florida	139,852.123	30,456.797	12,937,926	3,511,8
Michigan	147,135.821	12,547.912	9,295,297	2,439,1
Montana	376,990.894	3,858.589	799,065	211,666

49 Items

#### Counter

Selecting the counter option, the following window opens:

×	Widget	dil
	Configure data	
	42	
Use:	Select attribute	•
Operation:	Select attribute	-
Unit of measure:		

Also in this case the toolbar is similar to the one present in Chart section. The user is allowed to:

- Select the attribute to Use
- Select the **Operation** to perform
- Set the Unit of measure that will be displayed

Once the solution is clicked, the panel of the last step appears:

×	Widget	dil
Cor	nfigure Widget Info	
	49	
Title:		
Description:		
Also in this case the toolbar and ones in Chart section, with the missing. An example of counter widget of	only exception that the <b>Fi</b>	
* -	Unemployed people	1
7,7	44,8	24

# Manage existing widgets

Once widgets have been created, they will be placed on the bottom right of the map viewer and the *Widgets Tray* appears:

Through the buttons available on each widget the user can perform the following operations:

• Drag and drop the widget to move it within the map area of the viewer and **resize** it through the \_\_\_\_\_ button (also available for widgets present in a dashboard)

- **Pin** the position and the dimension of the widget through the 💉 button
- **Collapse** the widget through the button and expand it again by clicking the related button in the *Widgets Tray*

Make the widget Full screen through the 2<sup>nd</sup> button (also available for widgets present in a dashboard)

• Access to the *Title* and *Description* info through the 🕐 button, if this information has been provided during the widget configuration/creation

#### Access widgets menu

Once a widget is added to the map, it is possible to access its Menu through the

button. For *Text*, *Table* and *Counter* widgets, the following menu appears:

From here the user can:

• Edit the widget

#### . Delete the widget

Only for *Charts*, the menu is like the following:

In particular, the user can also:

- Show chart data in tabular representation
- Download data in .csv format
- Export Image in .jpg format

# Export Layer Data

MapStore allows to export both vector and raster layers present in TOC. In order to provide advanced export capabilities the WPS Download process must be installed and available in GeoServer. MapStore performs a preventive check for this as soon as the user opens the tool: if the WPS Download process is not available, MapStore uses the WFS service as fallback and the export options are limited (eg. only vector data can be exported). Once a layer is selected in the TOC, the user can open the **Export Data** tool by clicking the  $\bigcirc$  button available in the layer toolbar.

Export Data	×
Service	
WPS	•
File Format	
Select	•
Spatial Reference System	
Native	•
Crop dataset to current viewport	
Download filtered dataset	

Export

note
If the WFS service is the only one available, once the <b>Export Data</b> opens, the user can only select the <i>File Format</i> and the <i>Spatial Reference System</i> (as explained below).
Export Data
File Format
Select
Spatial Reference System
Native
⊙ Ехр
Only for the <b>Vector layer</b> , the user can also download data by opening the Attribute Table <b>from the TOC</b> and clicking the <b>O</b> button.

From the Export Data panel the user can:

- Select the **Service**, choosing between WPS and WFS (this option is present in the form only if the WPS Download process is available, otherwise the WFS service is used directly).
- Select the File Format. The list of formats depends on the availability of the WPS Download process in GeoServer. If the WPS process is available, the user can choose between GeoJSON, wfs-collection-1.0, wfscollection-1.1, Shapefile and CSV for vector layers, and between ArcGrid, TIFF, PNG, JPEG, in case of raster layers. If the WPS Download process is not available for some reasons, MapStore provides the list of formats valid for the WFS service by looking at the ones offered by the services capabilities (WFS Capabilities).
- Select the Spatial Reference System (By default Native or WGS84)

- Enable the **Crop dataset to current viewport** for downloading only the part of the layer visible on the map at that moment (this option is present in the form only if the WPS Download process is available)
- Only for *Vector layer*, allows to consider for the download also an eventual filter applied to the layer using the Filter layer tool (this option is present in the form only if the WPS Download process is available)

Export Data	×
File Format	
GeoJSON	-
Spatial Reference System	
Native	-
Crop dataset to current viewport	
Download filtered dataset	

• Only for *Raster layer* (and if the WPS Download process is available) the user can open the **Advanced options** to choose:

Export

- The **Compression type** used to store internal tiles ( CCITT RLE, LZW, JPEG, ZLip, PackBits or Deflate)
- The **Compression quality** for lossy compression (JPEG). Value is in the range [0 : 1] where 0 is for worst quality/higher compression and 1 is for best quality/lower compression
- Tile Width of internal tiles, in pixels
- Tile Height of internal tiles, in pixels

Export Data

File Format			
PNG			
Spatial Reference Sy	stem		
Native			
Crop dataset	to current view;	port	
<ul> <li>Advanced opt</li> </ul>	tions		
Compression	JPEG	× 🔻	
Quality	1		
Tile width	512	рх	
Tile height	512	рх	

Export

With a click on the  $\bigcirc$  Export button MapStore performs the export request. In case of WPS Download process available, multiple export requests can be performed from MapStore asynchronously. An information popup informs the user when an export process starts and the user can check the status of the process itself by opening the **Export Data Result** panel with a clicking on the  $\bigcirc$  button available on the right side of the footer.

The **Export Data Result** provides the list of exports processes started by the user and their status: as soon as the WPS completes the export operation, its status is reported by MapStore to the user (in progress, completed, and so ready for download, or failed). Therefore, the user can:

Export data results		
States of US	11/01/2021 10:12	

- Check for eventual reported errors: a specific icon informs the user that the process failed with a popup message.
- Download the final zip file: clicking the 💾 button
- $\cdot$  Remove the final zip file: clicking the  $\overline{1}$  button

# MapStore Toolbars

The main toolbar of MapStore, used by the user to interact on the map viewer, are:

- The Search bar
- The Side toolbar

## Search Bar

The search bar is a tool that allows the user to query the layers in order to find a specific information. In MapStore it is possible to perform the search in four different ways:

- By Location name
- By Coordinates
- By Configuring a search service
- By Bookmarks

### Search by location name

The Search by location name, set by default when a new map is created, allows the user to search places asking the OpenStreetMap Nominatim search engine. Typing the desired place, the Nominatim seach engine is queried; selecting then the desired record in the list of results, the map is automatically re-center/ zoomed to the chosen area that is also highlighted:

#### Search by coordinates

Performing a *Search by coordinates* the user can zoom to a specific point and place a marker in its position. That point can be specified typing the coordinates in two different formats:

• Decimal (the default format)

Lat	lat	Lon	lon	✿ < ≡

• Aeronautical (that can be chosen through the 🔅 button)

Lat	d	•	m	'	S	"	Ν	~	<b>A</b> 0 -
Lon	d	0	m	'	S	"	E	~	₩ ≪ =

Once the coordinates are set, it is possible to perform the search with the  $\mathbf{Q}$  button. The displayed result is similar to the following:

## Configuring a search service

MapStore allows the user also to extend or replace the default OSM results with additional *WFS Search Services*. Selecting the **Configure Search Services** option

 $\label{eq:stable}$  , the following window opens:

Create/edit a search service	×
Available services	
No Custom Services Defined	
Override default services	
	Add

In order to create a new custom service, the Add button brings the user to a page where he can set the *WFS service properties*, for example:

/FS service p	Tops	
Name		
My tiger_road	Is NAME WFS	
Service url		
https://demo	geo-solutions.it/ge	oserver/wfs
ayer		
tiger:tiger_roa	ds	
Attributes		
NAME		

In particular, the information to be entered are:

- Name of the service
- $\boldsymbol{\cdot}$  WFS Service URL the user want to call
- Layer to be queried
- Specific Attributes (comma separeted fields) the user wants to query

When all the options are set, by clicking on the Next button a new panel opens, where it is possible to choose the properties for the displayed results:

Title	
\$[properties	s.NAME}
Description	
Manhattan I	Roads
Priority 🖪	
Used to sort sea have priority - 5 Launch Info p	
Priority 3 Used to sort sea have priority - 5 Launch Info p No Info	

In this case, the user can define the following settings:

- The **Title** displayed on the top of each results row (in the previous image, for example, the chosen title for the results is the one corresponding to the attribute NAME of the feature)
- The Description to report in the results just below the title
- The **Priority**, a parameter which determines the position of the records in the results list. Lower values imply a higher positions in the results list and vice versa. By default the **OpenStreetMap Nominatim search engine** result has priority equals to 5, therefore in order to see the custom results in a higher position a lower priority value is needed
- The **Launch Info panel** allows the user to chose if and how the custom search interact with the Identify tool. In particular, with the *No Info* option, the Info panel doesn't show up once a record from the search results is

selected. Selecting *All Layers* or *Single Layer* the Identify tool is triggered, and the related panel opens displaying the information of all/single layer(s) visible in the map. With *Single Layer* instead, the Identify tool is triggered only for the layer (if it is present and visible in the map) related to the selected record in the search result list.

No Info	A
No Info	
All Layers	
Single Layer	

#### Note

Note that, selecting *All Layers* or *Single Layer* options, the point used for Identify request is a point belonging to the surface of the geometry of the selected record. Moreover, using *Single Layer*, the Identify request will filter results to the selected record and to its layer, using featureid which might be ignored by other servers, but can be used by GeoServer to select the specific feature of the results, when info\_format is other than *application/json*. In order to achieve filtering of feature on servers other than GeoServer, one can select the format (*info\_format*) as *application/json* for the layer to **GetFeatureInfo** from the layer settings in TOC to allow filtering features by using the ID of the selected record.

Once all the option are set, it is possible to move forward with the Next button Next that opens the *Optional properties* panel:

Create/edit a search service			$\times$
Optional props			
Sort by			
NAME			
Max features			
8	Back	Save/Upc	late

Here the user can choose:

- To Sort the results by the specified attribute
- The Max number of features (items) displayed in the custom search results
- The **Max** level of **zoom** to be set for the map when opening from the custom search result

After the Save/Update it is possible to see the custom WFS search service inside the Available services list:

Create/edit a search service	×
wailable services	
My Tiger_roads NAME WFS	N ®
Override default services	
	Add

Once a search service is created, it is always possible to Edit it  $\checkmark$  or Remove it from the list. By default the **Override default services** option is disabled, in that case performing a search not only the custom search service results are shown, but also the Nominatim ones:

rand	×
Grand Army Plz	
Ianhattans Roads	
Grand Army Plz	
Ianhattans Roads	
Grand Army Plz	
Ianhattans Roads	
Grand St	
Ianhattans Roads

## Search by bookmark

Select a bookmark	\$	0	$\equiv$
ThunderBay			
Vancover	5		

MapStore allows the user to search by the preconfigured bookmarks, which can zoom to a specific bounding box area or zoom along with reloading the visibility of the layers. Selecting the **Bookmark settings** icon, the following window opens:

In order to create a new bookmark, the Add button brings up **Add new bookmark** page where the user set the *Bookmark properties*, for example:

Add new bookmark		
Title Bookmark 1		
Bounding Box		<i>1</i> 9 🗮
	North	
	53,299368755339685	
West		East
-103.73510883068411		-69,98510883068413
	South	
	42.675974024765516	
		Back Save/Update

In particular, the information to be entered are:

- Title of the bookmark
- Bounding Box property the user wish to zoom to
- West, South, East and North
- **Toggle layer visibility reload**, **(1)** to enable/disable the layer visibility reload when searched by bookmark

Note: The user can define bounding box value either manually or by selecting **Use current view as bounding box** [1] to fetch the current bounding box values from the map view to populate the fields

When all the properties have been set, selecting the Save/Update it is possible to see the newly added bookmark in the **View bookmarks** list:

iew bookmarks	×
Filter bookmarks	<u>7</u>
ThunderBay	× 1
Vancover	× 1
Bookmark 1	<b>N</b>

Once a bookmark has been created, it is always possible to *Edit* it  $\bigotimes$  or *Remove* it  $\bigotimes$  from the list.

# Side toolbar

The *Side Toolbar* is an important component, positioned on the right side of the map viewer, that provides to the user the access to different tools of MapStore. The following tools are the ones available by default:

In particular, with these options it is possible to:

Go back to the Homepage by clicking the 🍙 button

- Login/Logout by clicking the button (for more information see the Managing Users and Groups section)
- Export map in json format by clicking the 🕢 button
- Import files from your computer by clicking the <a> button</a>
- Open the Catalog in order to connect to a remote service and add layers to the map by clicking the button
- Perform a Measure on the map by clicking the *state* button
- Save the map by clicking the 💾 button, in order to apply the changes made in an existing map. Selecting this option, the Resources Properties window opens, already filled with the current map properties
- Save as when the user needs to save a copy of a map or save one for the first time by clicking the button. Selecting this option an empty
   Resources Properties window opens.
- Delete Map in order to delete the current map by clicking the  $\overline{m}$  button
- Access the map **Settings** by clicking the substant button, where the user can change the current **Language** and select the Identify options

## Information sheet format

# Trigger event for the display of the information sheet

interview Note	
-	tion is enabled, opening the <b>Settings</b> panel, the editor is allowed to ons related to the <i>Cesium viewer</i> .
	Settings X
	Language
	Information sheet format
	TEXT -
	Trigger event for the display of the information sheet
	Click 🗸
	Map settings
	Show sky atmosphere
	<ul> <li>Show ground atmosphere</li> <li>Show fog</li> </ul>
	Enable depth test against terrain
•	

In particular, from the *Map Settings* it is possible to:

- Enable the Show sky atmosphere to see the atmosphere around the globe
- Enable the **Show ground atmosphere** to view the ground atmosphere on the globe when the camera is far away
- Enable the **Show fog** to allow additional performance by rendering less geometry and dispatching less terrain requests
- Enable the **Depth test against terrain** if primitives such as billboards, polylines, labels, etc. should be depth-tested against the terrain surface instead of always having them drawn on top of terrain unless they're on the opposite side of the globe
- See the **About this map** panel by clicking the button, when Details are present

- Share the map by clicking the < button
- Open the MapStore Documentation by clicking the 
   button
- Start the Tutorial by clicking the <u>I</u> button
- Know more information About MapStore and the deployed Version of MapStore by clicking the 
   button

#### MapStore

MapStore is a framework to build web mapping applications using standard mapping libraries, such as OpenLayers and Leaflet.

MapStore has several example applications:

- MapViewer is a simple viewer of preconfigured maps (optionally stored in a database using GeoStore)
- MapPublisher has been developed to create, save and share in a simple and intuitive way maps and mashups created selecting contents coming from well-known sources like Google Maps and OpenStreetMap or from services provided by organizations using open protocols like OGC WMS, WFS, WMTS or TMS and so on. For more information check the MapStore wiki.

#### License

MapStore is Free and Open Source software, it is based on OpenLayers, Leaflet and ReactJS, and is licensed under the Simplified BSD License.

For more information check this page.

#### Credits

MapStore is made by:

The **Save**, the **Delete Map** and the **Share** buttons are present in the *Options Menu* only when the map has already been saved once.

# Printing a Map

In MapStore it is possible to print a map by selecting the **Print** is button from Side Toolbar. The print process is composed by two main steps:

- Print Settings definition
- Result checking in Preview before download the printed file

## Print settings

As soon as the *Print* 🖶 button is chosen, the following window opens:

rint	
Title	Resolution:
My print	96 dpi
Description	
Enter a description	
Format	
PDF	<ul> <li>Image: A state of the state of</li></ul>
Coordinates System	
EPSG:3857	·
Layout	United States
Sheet size:	
A3	✓ México
Include legend	MEALU .
Legend on distinct page	- Charles
🔿 Landscape 💿 Portrait	Color
Legend options	
Legend options	© OpenStre

Through this window it is possible to:

- Enter a Title and a Description, that will be shown on the print page
- Change the Format ( PDF , PNG , JPEG )
- Change the Coordinates System (EPSG:3857, EPSG:4326)
- Change the **Resolution** of the print (96 dpi, 150 dpi, 300 dpi)
- Accessing Layout settings
- Accessing Legend options

### Note

In *Print settings* preview there's the map portion that will be displayed on the print sheet. In order to center the map the user can pan it until the preview displays the desired extension

← → C ☆ (≜ qa-mapstore.geosolutionsgroup.co	m/mapstore/#/viewer/openlayers/new

### Layout

Opening the **Layout** settings menu, the following menu appears:

Print	
Title	Resolution:
My print	96 dpi
Description	
Enter a description	
Format	
PDF	
Coordinates System	
EPSG:3857	·
Layout	United States
Sheet size:	
A3	▼ Mexico
🗌 Include legend	mento ap
Legend on distinct page	
🔿 Landscape 🛛 💿 Portrait	Colomb
Legend options	
Legend options	© OpenStree

From here, in particular, it is possible to:

- Select the Sheet size (choosing between A3 and A4 format)
- Choose to Include legend
- Choose to place the Legend on distinct page from the map
- Select the page orientation between Landscape and Portrait

## Legend options

The Legend can be customized through the **Legend options** menu:

Print	
Title My print	Resolution: 96 dpi
Description Enter a description	
Format PDF ~	
Coordinates System EPSG:3857	
Layout	United States
Legend options Labels Config: Verdana  Verdana  B I	Mexico
<ul> <li>Force Labels:</li> <li>Font Anti Aliasing:</li> </ul>	Colomb
Icons size:	© OpenStree
24	
Dpi:	
96	

Through this menu the user is allowed to:

- Configure labels by choosing font type and size, and by adding *Bold* and *Italic* style
- Enable the *Force Labels* option, that force the display of labels even if only one rule is present (by default, if only one rule is present, the label is not displayed)
- Enable the *Font Anti Aliasing* (when Anti Aliasing is on, the borders of the labels font are smoothed improving the image quality)
- Set the Icons size
- Set the Dpi resolution of the legend

## Preview

When the print settings are chosen, it is possible to access the preview by clicking on the **Print** button. A window similar to the following appears:

• Download the file in .pdf format

A simple printed map could be, for example, like the following:

My print

My description of the map

# Import Files

In MapStore it is possible to add map context files or vector files to a map. This operation can be performed by clicking ( from the Side Toolbar. Following these steps the import screen appears:

Here the user, in order to import a file, can drag and drop it inside the import screen or select it from the folders of the local machine through the

Select Files... button. Actually there's the possibility to import two different types of files:

- Map context files (supported formats: MapStore legacy format, WMC)
- Vector layer files (supported formats: shapefiles, KML/KMZ, GeoJSON and GPX)

#### Warning

Shapefiles must be contained in .zip archives.

# Export and Import map context files

A map context is, for example, the file that an user download selecting the  $\bigcirc$  button from the Side Toolbar. Map contexts can be exported in two different format:

• The MapStore file, is an export in json format of the current map context state: current projections, coordinates, zoom, extent, layers present in the map, widgets and more (additional information can be found in the Maps Configuration section of the Developer Guide).

Adding a MapStore configuration file the behavior is similar to the following:

• The WMC (Web Map Context) file, is a xml format where only WMS layers present in the map are exported including their settings related to projections, coordinates, zoom and extension (additional information can be found in the Maps Configuration section of the Developer Guide).

Adding a WMC configuration file the behavior is similar to the following:

# Import vector files

Importing vector files, the Add Local Vector Files window opens:

	eranen i		
san_andres_y_providencia_co	astline	•	
Stroke 2	-		
Default style			
<ul> <li>Zoom on the vector files</li> </ul>			

In particular, from this window, it is possible to:

• Choose the layer (when more than one layer is import at the same time)

- . Set the layer style or keep the default one
- Toggle the Zoom on the vector files

Once the settings are done, the files can be added with the Add button and they will be immediately available in the TOC nested inside the *Imported layers* group. For example:

#### 🛕 Warning

Currently is not possible to read the Attribute Table of the imported vector files and for this reason also the Layer Filter and the creation of Widgets are not allowed for those layers.

# Catalog Services

The Catalog Service for the Web (CSW) is an OGC Standard used to publish and search geospatial data and related metadata on the internet. It describes geospatial services such as Web Map Service (WMS) and Web Map Tile Service (WMTS).

In MapStore the Catalog offers the possibility to access WMS, WFS, CSW, WMTS and TMS Remote Services and to add the related layers to the map. By default, as soon as a user opens the Catalog, a CSW a WMS and a WMTS Demo Services are available, allowing to import layers from the GeoSolutions GeoServer. The user can access the Catalog with a click on the the button from the Side Toolbar. As soon as you open it, the first display is like the following:

-	Catalog	$\times$
Service		
GeoSolutions (	GeoServer CSW × 🗸 🔌	+
text to search		
Search		
	Meteorite_Landings_from_NASA_Open_Data_Portal	+
Preview Not Avaliable	mapstore:Meteorite_Landings_from_NASA_Open_Data_Portal	
	Types	+
Preview Not Avaliable	A simple layer with all the existing supported attriute types mapstore:Types	
	states	+
Preview Not Avaliable	mapstorestates	
	test.point +	<
Preview Not Avaliable	A layer that tests issues with layer names with points. See https://github.c_	
	mapstore:test.point	
	« < 1 2 3 4 5 6 × »	
	Results 1-4 of 22	
	500 km Scale: 1:18489335 •	₿ ⊕

# Adding Layers from Remote Services

In order to add a layer, the user can first of all open the catalog and choose from the following dropdown menu the Remote Service from where the layer is going to be added:

-	Catalog			×
Service				
GeoSolutions GeoServ	er WMS	×	•	+
GeoSolutions GeoServ	er CSW			
GeoSolutions GeoServ	er WMS			
GeoSolutions GeoServ	er WMTS			

Once the Remote Service is set, it is possible to search the desired layer by typing a text on the search bar:

AS	Catalog	×
Gdansk	Service	
dgoszcz mi Polska ewiesza	GeoSolutions GeoServer WMS	× 🔹 🔌 🕂
Łódź ubli aw Kraków	Search	
Slovensko Magyarország Clu	Preview Not Available States of US gs.us_states	+
Timisoara® Београд Sarajevo Србија Сrna Gora / Црна Гора София		
Shqipe +		

By clicking on the + button, the layer is finally added to the TOC and rendered to the map viewer:

#### Note

For those layers which have long descriptions or long metadata information, the content is truncated in order to fit the *Layer Card* size. In order to access the complete information, the user can expand the card using the **<** button:

Service			
GeoSolutions (	GeoServer CSW	•	+
text to search			
Search

	mapstore:test.point		
	« < 1 2 3 4 5 6 > »		

## Managing Remote Services

MapStore allows also to add new Remote Services to the map project ( + ) or Edit/Remove the existing ones (  $\checkmark$  ).

	Catalog			$\times$
Service				
GeoSolutions GeoServer CS	W	× 💌	٩	+
text to search				

The adding/editing process is very similar and the only difference is that editing an existing Service the input fields will be already filled with its settings, while adding a new one all the fields will be empty. Moreover only editing an existing Service, it will be possible to remove it from the Services list.

Editing an existing Service, for example, the first display is the following			-		_		_
בטוטווט מון פאוגטווט ספועוכפ. וטן פאמווטופ. נוופ וווגרטוגטומע וג ווופ וטוטשווט	Editina	on ovicting	Sorving for	ovomplo	the first	diaplay	ic the following
	Euliliu	anexisting	Service, IOI	example,		uispiay	is the following.

<u>/</u>	Catalog	×
Туре	Title	
CSW	▼ GeoSolutions GeoServer CSW	
Url		
https://gs-sta	ble.geo-solutions.it/geoserver/csw	
		-
Advanced s	settings	<
Save Delete	e Cancel	

From here the user is allowed to set the Service options, that can be divided into:

- General settings
- Advanced Settings

Once the options are properly set, it is possible to save the Service. If the user wants to discard the edits, instead, there's the cancel button. An existing Service can finally be removed from the Services list through the Delete button (this option is not available creating a new Remote Service).

## General settings

The general settings are three mandatory fields that each Remote Service needs to have:

<u>~</u>		Catalog	×
Туре		Title	
CSW		GeoSolutions GeoServer CSW	
Url			
https://gs-st	table.ge	o-solutions.it/geoserver/csw	
Advanced	l setting	gs	<
Save Dele	ete C	ancel	

In particular:

- Url: the URL of the remote source service
- **Type**: the type of the remote source service (between WMS, WFS, CSW, TMS, WMTS and 3D Tiles)
- **Title**: the title to assign to the catalog. This text will be used in the service selection dropdown menu for this service.

### Advanced settings

The Advances settings section opens by clicking on the *<* icon:

<b>/</b>	Catalog	×
Туре	Title	
CSW 🗸	type a title	
URL e.g. https://mydoma	ain.com/geoserver/csw	
Advanced setting	js	
Search on service	vice selection	
🛃 Show preview		

The content of Advanced settings depends on the catalog type, but some options are common to all the services types:

- Search on service selection that allow to enable/disable the automatic loading of the catalog records when the user opens that Service
- Show preview that can show/hide layers thumbnails in Catalog

# Catalog Types

## CSW Catalog

The Catalog Service for the Web (CSW) is an OGC Standard used to publish and search geospatial data and related metadata on the internet. It describes geospatial services such as Web Map Service (WMS), Web Map Tile Service (WMTS) and so on... MapStore actually supports only the **Dublin Core** metadata schemas. *ISO Metadata Profile is not supported yet*.

In **general settings of** CSW service the user can specify the title to assign to this service and the URL of the service.

<u>—</u>		Catalog	×
Туре		Title	
CSW		GeoSolutions GeoServer CSW	
Url			
https://gs-	stable.ge	o-solutions.it/geoserver/csw	
Advance	d settin	gs	<
Save De	lete C	ancel	

### **Advanced Settings**

<u>—</u>	c	Catalog	×
Туре	Title		
CSW 🗸	type a title		
URL			
e.g. https://mydor	main.com/geoser	ver/csw	
Advanced setti	ngs		<b>v</b>
Search on s	ervice selection		
Show preview	2W		
Set Visibility	/ Limit 🕜		
Show meta	data template		
Format		Select	-
Tile size (WMS)		256x256	× •
Server Type		Select	•

- Format: the default image format for the layers added to the map (png, png8, jpeg, vnd.jpeg-png, vnd.jpeg-png8 or gif). The format configured through this option will be automatically used for all layers loaded from the involved catalog source (if not configured a default image/ png is used). For layers already loaded on the map, it is possible to change the format through the Layer Settings tool as usual.
- Layer tile size: it represents tile size (width and height) to be used for tiles of all layers added to the map from the catalog source (256x256 or 512x512).
   For layers already loaded on the map, it is possible to change the tile size through the Layer Settings tool as usual.

 Server Type: to specify the server type of WMS online resources referred by metadata exposed by the CSW service URL. Possible options are two:
 Geoserver or No Vendor which can be for example MapProxy, MapServer or other.

#### Note

If the **No Vendor** is set, then MapStore will not use any vendor option supported only by GeoServer in the OGC requests where this source is involved.

- Set Visibility Limit: if checked and scale limits present in the WMS Capabilities (eg. MinScaleDenominator and/or MaxScaleDenominator), these will be automatically applied to the layer settings when a layer is added to the map from this source.
- Show metadata template: this can be enabled when the user wants to insert in the layer description a text with metadata information

#### Warning

The Metadata Template function is available for CSW Services only.

#### Metadata templates

In order to better understand this function, let's make an example supposing to edit the GeoSolutions GeoServer CSW service:

- Change the Format of the image that will be rendered on the map (png, png8, jpeg, vnd.jpeg-png, vnd.jpeg-png8 or gif) for layers belonging to the selected source
- Show metadata template can be enabled when the user wants to insert in the layer description a text with metadata information

Enabling the *Show metadata template* option appears a text editor through witch it is possible to insert the custom metadata information for that service. In order to dynamically parse each layer's metadata value the user can insert the desired properties name with the format *\${property\_name}*:

7	Catalog	
rl https://as-stable.or	o-solutions.it/geoserver/csw	
nups//gs/suble.g	o solutions to geosci vervesw	
ype	Title	
CSW •	GeoSolutions GeoServer CSW	
Advanced setting	5	~
<ul> <li>Search on service</li> <li>Show preview</li> <li>Show metadat</li> </ul>	Core format: abstract boundingBox, contribut creator, description, forr identifier, references, rig source, subject, temporal	tor, nat, hts,
lane en entre	e properties you need to display	
		P
\${description}		
Format	Select	
Save Delete	Cancel	

In this case it is possible to add a text like the following, in order to present desired metadata properties:

```
title: ${title}
_____
description: ${description}
_____
abstract: ${abstract}
_____
boundingBox: ${boundingBox}
_____
contributor: ${contributor}
_____
creator: ${creator}
_____
format: ${format}
_____
identifier: ${identifier}
_____
references: ${references}
_____
rights: ${rights}
_____
source: ${source}
_____
subject: ${subject}
_____
temporal: ${temporal}
_____
type: ${type}
_____
uri: ${uri}
```

Inserting this text and saving, the result should be that each layer will show its properties in catalog with the format we set:

Preview Not Avaliable	test.point	est.point								+ <
	ne_110m_									+ <
Preview Not Avaliable	gs:ne_110m	n_ocean								
Preview Not	poly_land									+ <
Avaliable	gs:ny_landr	narks								
Preview Not	poi									+ <
Avaliable	gs:ny_poi									
		ос с	1 2	3 4	5	6	>	*		
Note										

If some metadata are missing, the server response will be source Not Available

### Static Filter and Dynamic Filter

From the *Advanced Settings* of the *CSW catalog* the user has the possibility to configure a *Static Filter* and a *Dynamic Filter* to customize the search request.

In order to better understand this function, let's make an example supposing to edit the GeoSolutions GeoServer CSW service:

• From the *Static Filter* text area it is possible to insert the custom filter for that service.

In order to present desired *Static Filter* configuration, it is possible to add a text like the following:

```
<ogc:Or>
    <ogc:PropertyIsEqualTo>
        <ogc:PropertyName>dc:type</ogc:PropertyName>
        <ogc:Literal>dataset</ogc:Literal>
        </ogc:PropertyIsEqualTo>
        <ogc:PropertyIsEqualTo>
        <ogc:PropertyIsEqualTo>
        <ogc:PropertyName>dc:type</ogc:PropertyName>
        <ogc:Literal>http://purl.org/dc/dcmitype/Dataset</
ogc:Literal>
        </ogc:PropertyIsEqualTo>
        </ogc:PropertyIsEqualTo>
        </ogc:Cor>
```

Inserting this text and saving. The filter is applied, even in empty search.

• From the *Dynamic Filter* text area it is possible to insert the custom filter to applied in AND with *Static Filter*. The template is used with \${searchText} placeholder to append search string

# Catalog Туре CSW ~ Title GeoSolutions GeoServer CSW URL https://gs-stable.geo-solutions.it/geoserver/csw 4 <ogc:Literal>dataset</ogc:Literal> 7 <ogc:PropertyName>dc:type</ogc:PropertyNa 8 <ogc:Literal>http://purl.org/dc/dcmitype/ Dataset</ogc:Literal> Dynamic Filter 🕑 1 <ogc:PropertyIsLike wildCard='\*'</pre> singleChar='\_' escapeChar='\\'> 2 <ogc:PropertyName>csw:AnyText</ogc:Proper</pre> 3 <ogc:Literal>\${searchText}\*</ogc:Literal> Use template with \${searchText} placeholder to capture search string

In this case it is possible to add a text like the following:

```
<ogc:PropertyIsLike wildCard='*' singleChar='_' escapeChar='\\'>
<ogc:PropertyName>csw:AnyText</ogc:PropertyName>
<ogc:Literal>${searchText}*</ogc:Literal>
</ogc:PropertyIsLike>
```

Inserting this text and saving, the filter is applied when text is typed into the service search tool.

## WMS/WMTS Catalog

WMS and WMTS Services are OGC Standards protocol for publishing maps (and tile maps) on the Internet. The user can add these kind of services as catalogs to browse and add to the map the layers published using these protocols.

In **General Settings** the user can set the title he wants to assign to this service and the URL of the service to configure the service and its URL.

In addition to the standard options, only for WMS catalog sources, through the **Advanced Settings** the user can configure also the following options:

-	Catalog	X
Туре	Title	
WMS 🗸	type a title	
URL		
e.g. https://myd	omain.com/geoserver/wms	

dvanced settings		~
Search on service selection		
Show preview		
Enable localized styles		
🗌 Set Visibility Limit 🕜		
🗌 Single Tile 🝞		
Allow not secure layers		
Format	Select	•
Tile size (WMS)	256x256	× •
Server Type	Select	•

- Localized styles (only for the WMS service) if enabled allows to include the MapStore's locale in each **GetMap**, **GetLegendGraphic** and **GetFeatureInfo** requests to the server so that the WMS server, if properly configured, can use that locale to:
  - Use localized lables for Tiles in case of vector layers (the layer's style must be properly configured for this using the ENV variable support)
  - Produce a localized layer legend in case of vector layers (the layer's style must be properly configured to use the Localized tag for rule titles)

Produce a localized output for GetFeatureInfo requests (the freemarker template need to be properly configured to retrieve the locale from the request)

Enabling that option, all layers added to the map from this catalog source will be localized as described above (it is possible to tune again that setting for each single layer by opening the Layer Settings in TOC).

- Set Visibility Limit: available only for WMS layers coming from CSW or WMS catalog sources type. If checked and scale limits present in the WMS Capabilities (eg. MinScaleDenominator and/or MaxScaleDenominator), these will be automatically applied to the layer settings when a layer is added to the map from this source
- *Single Tile* (only for the WMS service): if checked, the layers loaded from the involved catalog source are rendered as a single tile. For layers already loaded on the map, it is possible to disable this option through the Layer Settings tool as usual.
- Allow not secure layers: if enabled allows the unsecure catalog URLs to be used (http only). Adding layers from WMS sources with this option active will also force the layer to use the proxy for all the requests, skipping the mixed content limitation of the browser.
- Format: the default image format for layers added to the map (png, png8, jpeg, vnd.jpeg-png, vnd.jpeg-png8 or gif). The format configured through this option will be automatically used for all layers loaded from the involved catalog source (if not configured a default image/png is used). For layers already loaded on the map, it is possible to change the format through the Layer Settings tool as usual.

#### Note

In case of WMS services, the list of available formats is retrieved from the WMS server

 Layer tile size: it represents tile size (width and height) to be used for tiles of all layers added to the map from the catalog source (256x256 or 512x512).
 For layers already loaded on the map, it is possible to change the tile size through the Layer Settings tool as usual. *Server Type*: to specify the server type of the used WMS service URL. Possible options are two: Geoserver or No Vendor which can be for example MapProxy, MapServer or other.

#### Note

If the **No Vendor** is set, then MapStore will not use any vendor option supported only by GeoServer in the OGC requests where this source is involved.

Domain aliases: available only for WMS catalogs type. This option is used to improve the performances of the application for tiled layer requests when multiple domains can be defined server side for the configured catalog source in MapStore (domain sharding). The user can configure multiple
 URLs referring to the same WMS service through the Add alias + button.
 Useful information about other kind of performance improvements can be found in the MapStore online training documentation.

### **TMS** Catalog

The Tile Map Service (TMS) specifications include some not official/not standard protocol for serving maps as tiles (i.e. splitting map up into a pyramid of images at multiple zoom levels). MapStore allows to add to the map the following services providers:

- Custom TMS service, specifying the URL template for the tiles.
- TMS 1.0.0 , setting the URL
- Select from a list of known TMS services, with all the variants.

Туре	Title
TMS •	My TMS serv
Provider	URL Template
custom 🔻	https://my-c
Custom TMS 1.0.0	
Stamen	gs Known online ervices

Select provider for TMS. The list of providers contains "custom", "TMS 1.0.0" and other resources

### Note

Since some of these services are not standard, using them in different CRSs may cause problems. Therefore, keep in mind that changing CRS can cause problems when these levels are on the map.

### **Custom TMS**

Selecting the **custom** provider the user can insert the tile URL template manually. The URL template is an URL with some placeholder that will be replaced with variables. The placeholder are identified by strings between brackets. e.g.: {variable\_name}.

<b>/</b>	Catalog	×
Туре	Title	
TMS	▼ My TMS service	
Provider	URL Template 🕢	
custom	<ul> <li>https://my-custom-service/[z]/[x]/[y].png</li> </ul>	
Custom TMS C	n service selection	
Save Cancel	]	

Edit a custom TMS

Allowed placeholder are:

- $\{x\}$ ,  $\{y\}$ ,  $\{z\}$ : coordinates of the tiles
- {s}: subdomains, this provides support for *domain sharding*. By default this is ["a", "b", "c"]. User can customize the default by adding options.subdomains.

example:

```
{
    "options": {
        "subdomains": ["a", "b", "c", "d", "e"]
```

} }

When the user saves this custom catalog service and clicks on search, he will see only one result, that can be added on the map: variants are not currently sopported in MapStore for this provider type.

× •	٩	+
		+
		1

Browse custom TMS service. It contains only one result

## Sample custom

url: https://{s}.tile.opentopomap.org/{z}/{x}/{y}.png

Sample custom with advanced options

```text url: https://nls-{s}.tileserver.com/nls/{z}/{x}/{y}.jpg

```
```json
{
    "options": {
        "subdomains": [
            "0",
            "1",
            "2",
            "3"
    ]
    }
}
```

## TMS 1.0.0

Selecting the "TMS 1.0.0" provider the user can insert the URL of the Tile Map Service (see TMS Specification). For instance, in GeoServer, it is the URL of the "TMS" link in the home page.

### **3D Tiles Catalog**

3D Tiles is an OGC specification designed for streaming and rendering massive 3D geospatial content such as Photogrammetry, 3D Buildings, BIM/CAD, and Point Clouds across desktop, web and mobile applications. MapStore allows to publish 3D Tiles contents in its 3D mode on top of the CesiumJS capabilities. Through the Catalog tool, a specific source type to load 3D Tiles in the Cesium Map can be configured as follows by specifying the URL of a reachable *tileset.json*.

In **general settings of** 3D Tiles service, the user can specify the title to assign to this service and the URL of the service.

# Performing Measurements

The Measure tool in MapStore allows the user to perform different kind of measurements (like distance, area and bearing etc.) on the map. It also provides some additional functionalities that are described in this section of the documentation. The tool is accessible from the Side Toolbar by selecting the *w* button that opens the following toolbar:

Through this window it is possible to:

## Measure distance

As soon as the measure window opens, by default the measure distance option is selected . In order to perform a distance measure, each click on the map correspond to a segment of the line (at least one segment is needed) while the double click inserts the last line segment and ends the drawing session.

The available units of measure are:

n	n	-
f	t	
n	n	
k	m	
n	ni	
r	m	

#### Note

The length of a line segment is shown on the map together with the measurement of the overall distance of all segments.

### Measure area

Once the **Measure Area** button is selected , it is possible to start the drawing session (in this case at least 3 vertices need to be indicated). Same as measuring the distance, each click correspond to a vertex and the double click will indicate the last one.

In this case the available units of measure are:

[	m²	•
1	ft²	
	m²	
	km²	
	mi²	
	nm²	
		_

note
Each side's length of the polygon is reported in map along with its perimeter and the area.

# Measure bearing

The Bearing measurements allows you to measure directions and angles. In the quadrant bearing system, the bearing of a line is measured as an angle from the reference meridian, either the north or the south, toward the east or the west. Bearings in the quadrant bearing system are written as a meridian, an angle and a direction. For example, a bearing of N 30 W defines an angle of 30 degrees west measured from north. A bearing of S 15 E defines an angle of 15 degrees east measured from the south.

After selecting the **Measure Bearing** button the user can draw a line with only two vertices that indicates respectively the starting and the ending point.

## Export the measure

Measurements drawn on the map can be exported in GeoJson format through the button.

## Add the measure as layer

Once a measure is drawn, it is possible to add it as a layer through the solution. The created layer is added to the Table of Contents as follows:

# Add measure as annotation

Once a measure is drawn, it is possible to add it as an Annotation through the button. The following panel opens:

From this step the creation process is the same described in the Annotations section.

### Measurement on the 3D navigation

When the 3D Navigation is enabled, the user has the ability to perform distance, area, point coordinates, height from terrain, angle and slope measurements on the 3D map.

#### Measure distance on the 3D navigation

As soon as the measure window opens, by default the **Measure distance in 3D** space option is selected  $3^{\circ}$ . In order to perform a distance measure, each click

on the map correspond to a segment of the line (at least one segment is needed) while the double click inserts the last line segment and ends the drawing session.

Measure area on the 3D navigation

Once the **Measure Area in 3D space** button is selected  $\Sigma^{\circ}$ , it is possible to start the drawing session (in this case, at least 3 vertices need to be indicated). Same as measuring the distance, each click corresponds to a vertex and the double click will indicate the last one.

Measure point coordinates

After selecting the **Measure point coordinates** button  $\bigcirc$  the editor can click on a point on the map and know latitude, longitude and altitude of that point.

### Measure height from terrain

Once the **Measure height from terrain** button is selected  $\mathcal{L}$ , it is possible to click on a point on the map and know the distance from the point to the terrain.

### Measure angle

Once the **Measure angle in 3D space** button is selected , the editor can draw three points on the map and get the angle value.

### Measure slope

Once the **Measure slope** button is selected **S**, the editor can draw three points on the map to create a triangular surface and get the slope value.

# Annotations

Mapstore lets you enrich the map with special features which expose additional information, mark particular position on the map and so on. Those features make up the so called **Annotations** layers.

Starting from a new map or an already existing one, the editor can access the **Annotations** — button from the TOC panel on the top-left corner of the map viewer.

The annotation panel will open:

# Add new Annotation

To begin, from the annotation panel, the editor can open the new annotation panel by selecting the + button.

From here the editor can insert a **Title** (required), a **Description** (optional) and choose between five different types of **Geometries**:

- Marker 💡 +
- Line 💦
- Polygon 📐
- Text  $T^+$
- Circle 🕑

After selecting a geometry type, the editor can:

• Draw a Geometry on the map.

• Enter the vertices of the geometry or modify the existing ones through the **Coordinates editor** using Decimal or Aeronautical formats.

• For *Line* and *Polygon*, add new vertices using the + button and typing the latitude and longitude values.

• Customize the **Style** of the annotation, as explained in the following paragraph.

Once the geometry has been saved through the **Save** button, for each geometry created, the editor can perform the following operations:

- **Zoom** to the geometry annotation on map through the  $[c_i]$  button
- $\cdot$  **Delete** the geometry annotation through the  $\ensuremath{\overline{10}}$  button

Once all the *Geometries* have been created, the editor can save the annotation through the **Save** button that will be visible in the annotation list:

Then, if not present, a new **Annotations** layer will be created and added to the TOC

# Styling Annotations

Based on which type of annotation was chosen, MapStore allows you to customize the annotation style through a powerful editor. It is accessible from the *Style* tab of the annotation viewer. During the style editing a preview placed on top of the styler form shows a preview of the edited style.

← 🗎			Polygon-test
	Title	Style	Coordinates
	Poly		
	Description		Polygon Style
≑ B I <u>U</u> �	Normal		_
T <sub>×</sub>	i≡ ≡ Z×	>	
	Description		<u> </u>
			ill
	1	1	Color
♥⁺ 以 以 T⁺	Geometries	20 %	Dpacity
gon-test 🛛 🛇 🔀 🖞	S Polygo		stroke
	<b>•</b>		ineDash .
	1	1	Color
	00%	100	Dpacity -
		3 bx	Vidth _

#### Marker

MapStore provides two types of *Marker* annotations, so you have to choose what type do you prefer using the *Type* combo box (*Marker* is the default):

Point		← 🕒
Coordinates	Style	Title
		Point
Marker Style		Description
īуре		Normal 🗘 B I <u>U</u> 🗞
уре	Marker 🔺	i≡ ≔ <i>I</i> ×
	Marker	Description
con	Symbol	Description
Shape	•	
		Geometries $\mathbf{Q}^+$ $\mathbf{k}^+_+$ $\mathbf{L}^+_+$ $\mathbf{T}^+$
		Point 🔍 🕄 🗑

• Marker types can be customized through the following editor:

	Ann	otations X
Point		▲
Coordina		int
Marker Style		cription
Туре		Jormal 🖨 B I 🖳 🗞
	TII	≡
Icon		escription
Shape		
		Geometries $\mathbf{Q}^+$ $\mathbf{h}^+$ $\mathbf{h}^+$ $\mathbf{T}^+$ $\mathbf{C}$
		🗣 Point 🔍 😒 📆

Choose the Shape, Color and Icon that best fit your needs.

• Symbol types can have different Shape and Size, a Fill color with a customizable Opacity level (%), a Stroke of different types (continuous, dashed, etc) and customizable Color, Opacity and Width. Only few symbols are provided by default in MapStore but a custom list of symbols can be configured.

Point		← 🗎
Coordinates	Style	Title
		Point
ymbol Style		Description
ре	Symbol 👻	Normal $\Rightarrow$ <b>B I U % E</b> $\equiv$ <b>I</b>
		Description
Layout		Geometries ♀+ 次 ½ T+ ( ♀ Point ♥ ※ 前
ize	Triangle C	
ill		
olor	/	
pacity	43 %	
stroke		
ineDash		
	1	
Color		
Color Opacity	100 %	

#### Polyline

*Polyline* annotations can be styled using the following editor:

	Anno	otations
Line		← 🗎
Coordinates	Style	Title
		Line
Polyline Style		Description
_		Normal ♥ B I U � I ≡ Ξ Ix
		Description
Stroke		
LineDash	•	
Color	1	Geometries $\mathbf{Q}^+$ $\mathbf{b}^+_{\mathbf{b}}$ $\mathbf{T}^+_{\mathbf{c}}$ (
Opacity .	100 %	🖒 Line 🔍 🗊
Width	3 px	8% Line
StartPoint Style		
EndPoint Style		
		500 km Scale: 1∶18489335 ✔

You can customize the Stroke in order to consider the Line/Dash type (continuous, dashed, dotted, etc), Color, Opacity and Width. You can also have styled *Start/End Points*: enable the StartPoint *Style/EndPoint Style* panel using the corresponding check box, the editor will be the same used for *Marker/Symbol annotations*.

#### Polygon

With polygonal annotations changing the style means choose the Shape and the size the Size of the polygon, its Fill color (with custom Opacity), the type of the Stroke (continuous, dashed, dotted, etc), its Color, Opacity and Width. See the example below to better understand these options.

Selve Polygon-test		← 🕒
Coordinates	Style	Title
		Poly
Polygon Style		Description
_	_	Normal 🗘 B I 🖳 🗞
<u> </u>		Description
Fill		
Color	1	
Opacity	20 %	Geometries $9^+$ $\mathbf{b}^+_+$ $\mathbf{b}^+_+$ $\mathbf{T}^+$ (
Stroke		🏂 Polygon-test 🔍 🗑
LineDash		L
Color	1	
Opacity	100 %	
Width	3 px	

#### Text

Text annotations are a bit different from the geometric ones. They display a formatted text on a given point of the map. The style editor allows you to customize the text Font (Family, Size, Style, Weight), the Alignment (left, center or right) and Rotation. You can also choose the text Fill color and its Opacity, the Stroke type, its Color, Opacity and Width. Take a look at the following example.

Text						+	8					
ext				Title								
Tijuana				Text								
Coordinates		Style		Description								
	Coordinates Style			Norr	mal 🛊 B	I U S	≡ ≡ <i>I</i> ×					
Text Style				Desci	ription							
7	ijuana											
				Geomet	rioc		0	- <u>8</u> +	₿* T*			
Font				Geomet	1103		•					
Family	Helvetica		-	Т	Text				0 9	Í		
Size	16	рх		-								
Style	italic		-									
Weight	normal		-									
Text												
Align	center		-									
Rotation	•		_									
Fill												
Color			1									
Opacity	<u></u>		100 %									
Stroke												
LineDash	-		-									
Color			1									
Opacity			100 %									
Width	1px											

#### Circle

Circle annotations can have custom Fill color (with custom Opacity), Stroke type (continuous, dashed, dotted, etc) with custom Color, Opacity and Width. The *Center* can be also customized through the same editor described for *Marker* annotations. See the example below.

Circle		← 🗎
Coordinates	Style	Title
Coordinates	Style	Circle
Circle Style		Description
0	S	Normal ♦ B I U � \ I = := Ix
1. A.		Description
Fill		
Color	1	
Opacity	20 %	Geometries $9^+$ $1^+$ $1^+$ $1^+$
Stroke		🕐 Circle 🖉 🖸
LineDash .		L
Color	1	
Opacity _	100 %	
Width	3 px	

Click on  $\checkmark$  to apply the style.

# Managing Annotations

Once annotations are added to the TOC, the editor can **Manage** them by clicking to solution from the TOC toolbar and the *Main Annotations panel* will be open.

From it, the editor is allowed to:

- $\cdot$  **Download** a file with all the existing annotations by clicking on  $\odot$  button
- **Upload** annotations from a valid json file by clicking on 📀 button
- $\cdot$  **Zoom** an annotation on map by clicking on  $\Im$  button
- Show/Hide an annotation on the map by clicking on 💿 button

From the *Main Annotations Panel*, by selecting an annotation from the list, the editor is returned to the *Annotation Viewer* where the annotation can be edited.

×	Annotations					
	← 🗊 💾 ⊙					
Title						
My annotat	tion					
Description						
Normal i≣ ा≣	ŧ B I U Ix	•				
Geometries	<b>♀</b> + % <del>,</del> 1	∠⁺ τ⁺ ⊘⁺				
🏷 Poly	gon	9				

In particular, the editor can:

• Change the *Coordinates* and the *Style* by clicking a geometry from list of geometries.

• **Download** the annotation in json format and reused in other maps by clicking on 💿 button

# Map Views

The **Map Views** is a MapStore tool useful to set up multiple map views differently configured and switch between them. A navigation functionality is also provided to automatically activate each view one after the other in temporal sequence.

The *Map Views* plugin works both in 2D and 3D modes, but the 3D mode has advanced options including the *Mask*, the *Globe Translucency* and the *Clipping* (see next paragraph).

### Add new view

Once the user opens a map, the *Map Views* tools can be opened through the button available in the Side Toolbar.

CESIUM Ion 🕬

To create a new simple view the user can simply move the map to the interested area, enable the desired layers in TOC to be displayed in the map and finally click on the + button. The view will be created and visible in the *Views* list by clicking the = button.

MapStore allows to customize and edit the new view by opening the Edit panel through the solution. Here the user is allowed to:

• Add a text, images, videos or hyperlinks through the **Description** section. The *description* is visible during the Views Navigation. Take a look at the following example.

• Capture the view positions through the Capture this view positions button or change the longitude, latitude and height of the Camera Position and Center Position (only available for the 3D mode) by using the **Position** section.

	N	lap View (1)	≣ + 🗈 🔊	<u>۲</u> ۲	₩	ĸ	►	×	»	
1ª	>	Description								
14	×	Position								
		Camera position								TOTO -
10		Longitude	Latitude	Height (m	1)					
		8.929333	44.401233	509						
-		Center position								
4		Longitude	Latitude	Height (m	1)					-
100		8.929333	44.401233	0						
		Capture this view p	ositions							-
-	>	Animation								
-	>	Mask								
	>	Globe Transluncency							N	
er.	>	Layers Options								
the second	-		No B	-	1	1				

• Modify the duration of the animation and enable/disable the transition effect during the Views Navigation by using the **Animation** section.

• When in 3D mode, use the **Mask** section to select a WFS or Vector layer available in TOC to create a mask on all the 3D tiles visible in map. The mask layer need to be added to the map before using this functionality so that it is possible to use the layer features as masking areas: if multiple WFS or Vector layers (with polygonal features) are present in the map, these are used all merged together to represent the final masking areas.

If the user enables the **Inverse** option, simply the inverse mask is applied using the same layer so that each feature is used to produce an hole on all visible 3D Tiles.

• Enable the translucency of the globe through **Globe Translucency** section so that it is possible to see layers under the globe's surface.

• Choose which layer should be visible when the view is active through the **Layer Options** section. In 2D mode the user can simply enable or disable all the layers present on TOC and change the opacity.

In 2D mode, the 3D Tiles and the Terrain layers are not displayed in the Layer Options.

In *3D mode*, using the same logic described above for the Masking option, it is also possible to Clip (not Mask) each 3D Tiles or Terrain layers using a WFS or a vector layer as a clipping source. Furthermore, in this case the user can also choose which layer feature can be used as *Clipping feature*.

#### Warning

The clipping layer must have polygon convex features. Concave polygons are not supported by this type of clipping.

#### Note

Unlike the *Mask* option, described above, the *Clip function* is a more narrowly focused tool because:

- The clipping are is visible only on the selected 3D Tiles layer and not on the whole view
- It is possible to select the feature of the WFS or Vector layer that you want to use for the clipping

### **3D Views navigations**

Once multiple views are added to the *Map Views* tool it allows to visualize them in sequence by clicking on the button. Doing that the presentation mode starts and each view is displayed in the Map Viewer, together with its descriptive panel (if configured) on the left side of the screen, for a time depended on the duration previously configured.

The user can also choose to navigate each view manually using the navigation toolbar provided by the tool.

# Street View

The **Street View** tool allows the user to browse Google Street View contents in MapStore. Through the **MapStore** button available in the Side Toolbar, the tool can be activated so that it is possible to navigate the map with Google Street View.

When the tool is activated, a window opens and the streets highlighted on the map so that the user can select one of them with a simple click of the mouse.

By clicking on a street in the map, the tool window displays the Street View and the user can navigate it as usual.

• Use the **Pan Interaction** to navigate all-around the street

Enable/disable the Full Screen

#### 🖍 Note

By default, the **Street View** plugin is ready to be configured for application contexts, and is not available in the default plugin configuration due to licensing reasons.

# Navigation Toolbar

The *Navigation Toolbar* is a navigation panel containing various elements that help the user to explore the map. In particular, it is possible zooming, changing the extent, navigating in 3D mode and querying objects on the map. Moreover, the following icon •••• is used to expand/collapse the navigation toolbar.

# Geolocation tool

Through the *Show my position* 💮 the user can center the map on his position. Therefore the button turns green.

The position is still active even when the user interacts with the map; with a single click on the button it is possible re-center the map on his position. To disable the position the button needs to be duble clicked.

# Zooming tools

MapStore provides several tools allows the user to:

- Increase the map zoom by using the zoom in icon
- Decrease the map zoom by using the zoom out icon
- Switch to full screen 53 view
- Go back [] to the previous map extent in the map navigation history
- **Go forward I** to the next map extent in the map navigation history
- Zoom to the maximum extent 🛃 the map

# **3D** Navigation

The *3D navigation* in MapStore is based on CesiumJS. If the 3D button **3D** in the *Navigation Toolbar* is clicked, the map switch in 3D mode so map contents are displayed on a 3D globe and it is possible to orbit around it through the compass place in the upper right corner of the map.

### 🖍 Note

The *3D mode* in MapStore support also the rendering **3D Tiles** layers once they are added through the *Catalog tool* as explained here.

# Identify Tool

The *Identify* tool **Q** allows to retrieve information about layers on the map. The tool is active by default (the button is green). Therefore if the user click on a layer in the map, the identify panel opens containing the layers information corresponding to the clicked point in the map (also the coordinates of the clicked point are reported in the identify panel).

The layers information are reported in plain text by default. It is possible to change the format by selecting the 🏠 button in Side Toolbar where the user can select, through the *Identify response format* menu, three different formats like: **TEXT**, **HTML** and **PROPERTIES**.

Settings	×
Language	
Identify response format	
TEXT	•
TEXT HTML	
PROPERTIES	2

The information will be returned in the format chosen by the user. For exaple with *PROPERTIES* format as follows:

In addition to the layers information, the following are provided by the *Identify Tool*:

• The **point address** through the *More Info* button **(**)

• The coordinates  $\bigcirc$  of the point

#### Note

The point coordinates are visualized in **decimal** or **areonautical** format. It is possible to change the format by the *setting* button

• The **Highlight Features** button if allows to highlights on the map the layers features corresponding to the retrieved information in the clicked point.

• The **Edit** button showing only layers records corresponding to the clicked point on the map.

### Using the Coordinates Editor

In order to Identify layers features by typing coordinates instead of clicking on the map, you can use the **Coordinate Editor**.

The coordinates can be in **decimal** or **areonautical** format depending on the user needs. It is possible to change the format by the *setting* button

An example of search with Decimal coordinates as follows:

An example of search with Aeronautical coordinates as follows:

## Identify Tool with more than one layer

In a map it is possible to have several overlapping layers. With the *Identify* tool the user can retrieve information on one or more overlapping layers at the same time in a certain point.

If the user clicks on the map where one or more overlapping layers are present, the identify panel opens. The panel provides the layers information, therefore the user can navigate different layers information from the **layer select** drop-down menu where the layer options have been sorted as in *TOC*.

In order to have information about one layer only the user can select the layer on the Table of Contents, through the *TOC* button , and then click on the layer in the map to perform the identify operation only for that selected layer in TOC. The identify panel opens containing the layer information corresponding to the clicked point in the map, as follows:

## **Floating Identify Tool**

In MapStore the user can set the Identify tool in floating mode (**Floating Identify tool**) instead of having the default one available through a click on the map. In that case an identify popup will appears on the map as soon as the user hover over a layer in the map.

In order to activate the *Floating Identify Tool* the user can select the **b**utton in Side Toolbar. Here he can select the **Hover** option through the *Trigger event for Identify* dropdown menu.

Settings	×
Language          Image       Image         Identify response format         TEXT	•
Trigger event for Identify	
Click	•
Click	
Hover	

As soon as the option *Hover* is selected, the user can hover the mouse over a layer in the map in order to show the popup containing the identify information.

# Background Selector

The background selector, located in the bottom left corner of the *Viewer*, allows the user to add, manage and remove map backgrounds.

By clicking on the background selector several miniatures will be displayed. Those miniatures can be selected in order to switch from a background to another (the map backgrounds set by default in MapStore are *Open Street Map*, *NASAGIBS*, *OpenTopoMap*, *Sentinel 2* and the *Empty Background*).

For example choosing *OpenTopoMap*, the map background will change like in the following image:

If the user has editing permissions on the map (independently on the role, see **Resource Properties** section for more information about permissions), it is also possible to add, edit or remove backgrounds.

# Add background

A new background can be added through the + button on the top of the background selector main card. Performing this operation the Catalog panel opens with the possibility to access the *Remote Services*:

7	Catalog	>
ervice		
Default Ba	ckgrounds	× +
Default Ba	ckgrounds	
GeoSolutic	ons GeoServer CSW	
GeoSolutio	ons GeoServer WMS	
GeoSolutic	ons GeoServer WMTS	
	Open Street Map	Added to background selector
	Open Street Map	
	mapnik	
S. A. C.	NASAGIBS Night 2012	Added to background selector
	NASAGIBS Night 2012	
	Night2012	
	ОрепТороМар	Added to background selector
100	ОрепТороМар	
623	ОрепТороМар.	
12.3	Sentinel 2 Cloudless	Added to background selector
	Sentinel 2 Cloudless	
6	szcloudless:szcloudless	

Results 1-4 of 5

#### 🛕 Warning

Default Backgrounds service is available only accessing the Catalog from the background selector, but if you add a new Remote Service from there, it will be available also accessing Catalog from the Side Toolbar or from TOC. *Default Backgrounds* represent a list of backgrounds that can be configured from MapStore's configuration files (more information about that can be found in Developer Guide's Map Configuration section).

From the Catalog the user can choose the layers to add to the list of backgrounds:

	ne_110m_ocean	+
Preview Not	ne_110m_ocean	
Available	gs.ne_110m_ocean	

As soon as a WMS layer is selected, the Add New Background window opens:

In particular, from this window, the user can perform the following operations:

- Add a **Thumbnail** choosing the desired local file by clicking on image preview area, or simply with the drag and drop function
- Set the **Title**
- Set the Format (between png, png8, jpeg, vnd.jpeg-png or gif)

- Choose the Style, between the ones available for that layer
- Add **Additional Parameters** of three different types: *String, Number* or *Boolean* (these parameters will be added to the WMS request).

Once the options are chosen, with the Add button the new background layer is definitively added to the background selector as a card and automatically set as the current one.

### Add WMTS background

In case of a WMTS layer added as a background layer, the **Add New Background window** is a bit different:

Add

The user can perform the following operations:

- Add a **Thumbnail** choosing the desired local file by clicking on image preview area, or simply with the drag and drop function
- $\boldsymbol{\cdot} \, \text{Set the } \textbf{Title}$
- Set the Attribution visible at the bottom left of the footer in the map viewer.

# Edit background

It is possible to edit backgrounds by clicking on settings icon on top of each background card:

Default Backgrounds layers can't be edited, with an exception for Sentinel 2: only WMS Layers can be edited&/configured through the Background Selector.

The **Edit Current Background** window opens, allowing the user to customize the same set of information when adding a new background (see previous section).

# Remove background

It is possible to remove a background from the background selector by clicking on remove icon on top-right of each card

#### Note

By default, for new maps, all backgrounds from *Default Backgrounds* Service are added to the background selector, and in Catalog they appear grayed (it's not allowed to add the same default background twice): as soon as you remove one from the background selector, it becomes selectable from the Catalog.

# Timeline

The Timeline is a MapStore tool for managing layers with a time dimension. It makes possible to observe the layers' evolution over time, to inspect the layer configuration at a specific time instant (or in a time range) and to view different layer configurations time by time dynamically through animations.

#### Warning

The Timeline tool currently works only with WMS layers from GeoServer where the WMTS-Multidim extension is installed (WMS time values in WMS Capabilities is not supported yet). To use the MapStore Timeline at least **GeoServer 2.14.5** is required, but the recommended version is **GeoServer 2.15.2** to have a complete support for all of the features the Timeline tool can provide (e.g. the filter by viewport). From now on, the layers that the Timeline can manage will be addressed as *time layers*. From now on, the layers that the Timeline can manage will be addressed as *time layers*.

When a layer with a time dimension is added to the map, the Timeline panel becomes automatically visible and it allows the user to browse the layer over time.

Note

Widgets and Timeline cannot be expanded on the same map at the same time. See this section to learn more about this.

# Timeline histogram

The Histogram panel opens through the **Expand time slider** button

In the Histogram panel some of the most relevant elements are the following ones:

- A list of layers present in map with the time dimension available. It is possible to hide this list with the **Hide layers names** button
- The relative histogram that shows the layer' data for each time in which it is defined. In order to manage the panel the user can zoom in/out on the histogram, scroll the time axis and drag the current time cursor along it

# Set a Time Range

In order to see a layer in a specific time instant the user can insert a data and a time in the panel, as follows:

In order to observe the layers in a finite fixed time interval the user can set a time range through the **Time range** button **()**. A date/time control panel opens to set the range limits either by directly entering values in those cells or by dragging the limits cursors along the histogram time axis, as follows:

### Reset timeline

Based on the timeline configuration, the reset button *S* can be made visible on the timeline toolbar. It allows the user to reset the time data based on the current mode of the timeline

- When the current mode is **single**, the icon is represented as  $\bigcirc$ , and the layer is *selected* in timeline, the time is set to nearest of now and when the layer is *not selected*, the time is set to now
- When the current mode is **range**, the icon is represented as ↔, the time is set to the full range of the layer

# Show times available on map

Sometimes you might be interested to show in the timeline histogram only the times instants currently visible on the map, especially when you are exploring a big data set. This feature can be enabled by clicking the **Map Sync** button  $\Im$ . When this tool is active the timeline will show only the times of the features available in the current map viewport.

# Animations

The user can start a time animation by using the timeline tool through the following buttons (by default the animation of layers in map is based on time values related the **guide layer**, see the Animation Settings section > Timeline Settings > Snap to guide layer option):

In order to start the animation the user can click on **Play** button **>**. Once the animation is started, the temporal layers in map are updated accordingly and the user can see the animation progress also in the timeline histogram. Following the sequence of steps, the cursor will shift each time to the next step in a certain time interval, the *frame duration*.

Through the **Stop** button the user can stop the animation and the current time cursor remains in the last position reached.

The **Step backward** button is and the **Step forward** button is allow the user to change the current time. Therefore, by clicking on one of them, the cursor changes its position (to the previous or the next step) on the histogram, the date/time values of the control cells will be updated accordingly and the layers in map are updated too.

The user can pause the animation through the **Pause** button **III**, as follows:

#### Note

The user can also specify a *time range*. During the animation, the whole range will be shifted step by step along the time axis and, in each step, the layers in map will show data corresponding to that range of time.

## **Animation Settings**

The animation behavior can be customized through the **Settings** button . It allows the user to tune the *Timeline* and the *Playback* options.

Snap to guide	layer 🕜 📃	
Time interval s	snap point 🕜	
Start	⊖ End	
Playback	Layers	
Frame Duratio	n	
2		🗘 s
Animation Ste	р 🕜	
1	🗘 Day 🗸	
Animation Ra	nge	

By default, the **Snap to guide layer** is enabled. It allows to force the time cursor to snap to the selected layer's data.

Snap to guide	layer 🕜 📃	
Time interval s	nap point 🕜	
Start	⊖ End	
Playback	Layers	
Frame Duratio	n	
2		Ĵ s
Animation Ste	p @	
1	🗧 Day 🗸	
Animation Ra	nge	

If the time dimension of the layer has time ranges defined (start/end time) instead of time instants, the user can choose the **Time interval snap point** by selecting the option Start or End. An example of snapping to the End point could be the following:

The user can disable *Snap to guide layer* to select the preferred time step through the **Animation Step** option. For example, the process could be similar to the following one:

	layer 🕜 🔄	
Playback	Layers	
rame Duratio	n	
2		‡ s
Animation Ste		
1	C Day	~

The user can set the number of second between one animation frame and another through the **Frame Duration** and enable the **Follow the animation** to

visualize the animation process also inside the histogram: the histogram will automatically move to follow the animation.

Playback	1	Laye	ers		
rame Dura	tion				
2					¢ s
nimation S	itep 🕜				
1		\$	Day	~	
Animation	Range				

Enabling the **Animation Range** the user can bound the animation execution to a fixed time interval, the *green range*. The *green range* can be defined both dragging the *play/stop cursors* directly on the histogram or filling the *date/time control cells* of the extra panel displayed, as follows:

In order to properly set the Animation Ranger, some controls are available to help the user:

- Zoom the histogram until it fits the animation's *green range* time extension through the **Zoom to the current playback range** button **Q**
- Extend the animation's *green range* until it fits the current view range of the histogram through the **Set to current view range** button ↔
- Extend the animation's green range until it fits the guide layer time extension through the **Fit to selected layer's range** button

# Layers Setting

The **layers** tab lists all the available time layers present in the map. The user can toggle a layer to be *shown/hidden* in the timeline by clicking on the checkbox next to the layer title.

## Footer

In MapStore some of the map information are reported in the *Footer*. By default, as soon as the user opens the map, the scale bar and the scale switcher are showed so that the user can change the scale bar by zooming in/out the map or by selecting a map scale through the scale switcher.

1000 km	Scale:	1:18468637

In order to visualize the map coordinates corresponding to the mouse pointer in the selected *Coordinate Reference System* of the map, the user can click on the button

Coordinates:	X: 1,035,318.78 Y: 2,362,114.64	CRS:	EPSG:3857	
--------------	---------------------------------	------	-----------	--

### **CRS** Selector

MapStore allows also to change the *Coordinate Reference System* of the map by clicking on the **Select Projection** button ①. A CRS selector opens to select one of the available CRSs, as follows:

The list of available CRSs depends on the CRS Selector configuration.

In order to search a desired CRS, the user can also filter the CRS list by typing in a search input field.

# Exploring Dashboards

In MapStore, a *Dashboard* is a space where the user can add many Widgets, such as charts, maps, tables, texts and counters, and can create connections between them in order to:

- 1. Provide an overview to better visualize a specific data context
- 2. Interact spatially and analytically with the data by creating connections between widgets
- 3. Perform analysis on involved data/layers

In order to create a new dashboard, the **New Dashboard** button appears in MapStore Homepage once logged as Administrator or Normal user. With a click on it, an empty dashboard workspace appears. This page is composed of a *Topbar*, a *Sidebar* and a *Viewer*:

### Topbar

Through the Topbar it is possible to:

- Set the language, with the Language switcher:

- Go back to the Homepage with the 
   button
- Take a look at the account info, change password and logout, with the button (more info about these options are available in Managing Users and Groups section)

#### **Options Menu**

In the **Options**  $\equiv$  drop-down menu you can:

- - ABOUT
- Export dashboard in json format
- **Import** dashboard in json format (it will replace without asking the current dashboard)

- . Save/Save as the dashboard
- Delete the dashboard
- Open the Share panel
- Start the Tutorial
- See the information about the deployed **Version** of MapStore in the **About** panel.

#### About

### MapStore Version

Version	2022.02.xx-qa
Message	#8580 Unmute epics on plugin registration (#8583) (#8585)
Commit	6191402349d6d286fff27e6e3c8df0e5825927a8
Date	Tue, 13 Sep 2022 17:52:20 +0300

### MapStore

MapStore is a framework to build web mapping applications using standard mapping libraries, such as OpenLayers and Leaflet.

MapStore has several example applications:

- MapViewer is a simple viewer of preconfigured maps (optionally stored in a database using GeoStore)
- MapPublisher has been developed to create, save and share in a simple and intuitive way maps and mashups created selecting contents coming from well-known sources like Google Maps and OpenStreetMap or from services provided by organizations using open protocols like OGC WMS, WFS, WMTS or TMS and so on. For more information check the MapStore wiki.

#### License

MapStore is Free and Open Source software, it is based on OpenLayers, Leaflet and ReactJS, and is licensed under the Simplified BSD License.

For more information check this page.

#### Credits

MapStore is made by:

#### Sidebar

The Sidebar allows the user to:

- Add new widgets with the + button
- See the connections between widgets with the *Q* button, available when connections are present (more information about this option are available in Connecting Widgets section)

#### Viewer

Once the widgets are added in the viewer it is possible to:

• Change widgets position by moving them with a simple *Drag and Drop* and resize them:

• Access widgets menu from which the user can choose between several options (more information about this menu's options can be found in Map's Access Widget Menu section)

. Take a look at the widget *Description* (more information about widget *Description* can be found in Map's Access Widgets Info section)

# Adding Widgets

With a click on the + button in Sidebar the *Widget* panel opens, showing the list of the available widget types that can be added to the dashboard:

In particular, it is possible to choose between:

- Chart
- Text
- Table
- Counter

#### Мар

Creating *Chart*, *Text*, *Table* and *Counter* widgets the procedure is almost the same as that described for create widgets in maps. The only minor differences are the following:

 In dashboards as soon as the user selects the widget type, a panel appears to select the layer from which the widget will be created. MapStore allows you to choose between CSW, WMS and WMTS GeoSolutions Services, present by default, or by accessing WMS, WFS, CSW, WMTS and TMS Remote Services as explained in the Managing Remote Services section

×	Widget		dil							
	Select a layer									
GeoSolutions	GeoSolutions GeoServer CSW × 🔺									
GeoSolutions	GeoSolutions GeoServer CSW									
GeoSolutions	GeoSolutions GeoServer WMS									
GeoSolutions	GeoSolutions GeoServer WMTS									
	test:Linea_costa									
	areeverdiPolygon test:areeverdiPolygon									

 In dashboards the possibility to connect/disconnect widgets to the map is replaced with the possibility to connect/disconnect the Map widgets together or with other widget types (this point will be better explained in Connecting Widgets section)

Creating Map type widgets, otherwise, is a functionality present only in dashboards.

## Map Widget

In dashboards, selecting the Map type widget, the following panel appears:

Here the user can:

- Go back to widget type selection through the
- · Search for a map by writing its title
- Select one or more maps from the list of maps (mandatory in order to move forward)
- Move forward to the next step through the 
   button

Once a map has been selected, the panel display the layers present in the map in the preview and lists the layer associated with the map. Note

If user has selected more than one map, the map wizard displays the *map switcher* dropdown allowing user to select and configure the map.

On the **Configure map options** panel the user can toggle the layer visibility and set layers transparency, as explained in **Display options** section. Furthermore, the user can manage the layer with the new buttons present on the layer toolbar by selecting the layer on the layers list.

Here, the user is allowed to:

- Zoom to layers though the 🚫 button
- Access Layer Settings through the 🔧 button
- Remove layers through the 👘 button
- Disable/Enable the Floating Identify Tool to retrieve Identify information about layers available on the map through the 🕖 button

Once the solution is clicked, the last step of the process is displayed like the following:

×	Widget	dtl
	← 🗎	
C	Configure Widget Info	
Title:		
Description:		

Here the user has the possibility to insert a **Title** and a **Description** for the widget (optional fields) and to complete its creation by clicking on the that, the widget is added to the viewer space:

## Legend widget

When at least one Map widget is created and added to the dashboard, there's the possibility to add also the **Legend** widget, available in the widget types list:

Selecting the Legend widget, the user can choose the Map widget to which the legend will be connected (when only a Map widget is present in the dashboard this step is skipped):

Once a Map widget is connected, the preview panel is similar to the following:

1

×	Widget	dth
	Preview	
sfdem		
values		
values values values values		
restricted		
RedFill	RedOutline	
roads		
/ Roads		
bugsites		
<b>O</b> Capita	s	

Here the user can go back < to the widget types section, connect or disconnect to a map and move forward to widget options. If the last option is selected, a configuration panel similar to the Map widgets one gives the possibility, before save, to set the *Title* and the *Description* for the

Legend widget.

An example of a Map widgets and a Legend widget is the following:

## Connecting Widgets

In dashboards it is possible to connect the added widgets allowing the user to inspect and interact with more than one of them at the same time.

Once at least one connection between widgets is set, it is possible to identify the connected widgets turning on the connections button in the dashboard Sidebar making it green . This will highlight the connected elements with a colored bar on their upper side.

In general, you can connect:

- Map widgets with other widgets
- Table widgets with other widgets

### Connecting Map widgets with other widgets

In dashboards it is possible to connect Map widgets with:

- Other Map widgets
- Chart widgets
- Table widgets
- Counter widgets
- Legend widgets

#### Maps with other Maps

As soon as more than one Map widget is added to the dashboard, the connect/ disconnect button appears inside the *Configure map options* panel (accessible by adding a new Map widget or editing an existing one).

With a click on it, if only another Map widget is present, by default the connection will be made towards that Map widgets. When more than one Map widget is present in the dashboard, instead, it is possible choose one through a page like the following:

#### Maps with Charts, Tables and Counters

In order to connect Charts, Tables or Counters widget with Maps widget, the procedure is similar to that seen in the previous section. The result is that the

information displayed in the Chart, Table or Counter changes accordingly with the map portion displayed in the connected Map widget. For example the result could be:

Connecting Charts with Maps:

• Connecting Tables with Maps:

Connecting Counters with Maps:

When a pan or zoom operation is performed in the Map widget, the other connected widgets are spatially filtered according to the Map viewport.

#### Maps with Legends

Also in this case the connecting procedure is similar to those seen previously, but now the information contained in the Legend widget doesn't change according with the map extension. An example can be the following:

### Connecting Table widgets with other widgets

With the same procedure used for maps (see previous section) the user can connect Table widgets with:

- Map widgets
- Other table widgets, only if it refers to the same layer
- Chart widgets, only if it refers to the same layer
- · Counter widgets, only if it refers to the same layer

When a table is connected with other widgets, it became a *Parent Table* and a filter appears on the top.

A Map widget that is connected to a Parent Table receives the alphanumeric filter of the Table and:

- Performs a zoom to the extent that contains all the Table widget records (the result of the filter in the Table)
- If the Map widget contains the same dataset (layer) of the Parent Table, also the layer on map is filtered accordingly

Once a widget is connected to a map widget that is connected to a Parent Table at the same time:

• If the widget has been created on the same dataset (layer) of the Parent Table then two filters will be applied in AND to the widget itself: the spatial filter of the Map widget and the attribute filter defined in the Parent Table

There are different combinations of connections, the image below illustrates the allowed ones by reporting also the kind of filters applied for each case

# Exploring Story

In MapStore, GeoStory is a tool that allows to create inspiring and immersive stories by combining text, interactive maps, and other multimedia content like images and video or other third party contents. Through this tool you can simply tell your stories on the web and then publish and share them with different groups of MapStore user or make them public to everyone around the world.

The user can approach a story in two different ways:

- Creating a new story or editing an existing one through the Edit Mode
- Enjoy the story and interact with it, through the View Mode

### Edit Mode

The *Edit Mode* allows the user to edit a story by adding, removing or modifying the elements inside it. This mode and its tools are used both to edit an existing story and to create a new one.

In order to create a new story, the user can click on the **New GeoStory** button on MapStore home page. As soon as the user clicks on that button in home page the story editor opens, it is composed of three main elements: the Topbar, the *Builder* and the *Sections Container* (later simply called *Container*).

Actions	Top Bar	
1 G + V	× 8	
T Abstract yype: title		
	<b>い主/</b> 町	
	Insert title	
Builder	Sections Container	
builder		
	+	

The Story content is organized in Sections, that can be added with the **+** button in the *Container* area. In particular, the user can add to the story the following kind of sections:

_	Title	Banner	Paragraph	Immersive	GeoCarousel	Media	W
_	T		§≣		≣ ♥		[
			_			—	-
-							
				+			

- Title Section
- Banner Section
- Paragraph Section
- Immersive Section
- GeoCarousel Section

- Media Section
- Web Page Section

### View Mode

The *View Mode* corresponds to the final result of your story composition that will be visible to end users on the web.

The user can access the *View Mode* also during the Story editing in order to have a preview of its work on the Story itself. The **Show preview** button in Builder's toolbar allows to do that and the first display looks like the following:

This is a list of the highest astronomical observatories in the world, considering only ground-based observatories and ordered by elevation above mean sea level. The main list includes only permanent observatories with facilities constructed at a fixed location, followed by a supplementary list for temporary observatories such as transportable telescopes or instrument packages. For large

On top of the page there is a **Top bar** in which the story's informations (if properly configured in edit mode) are displayed.

In part in a second second second second second devices between the second secon

The elements available in the top bar can be the following:

- Edit Story button 🔨 that allows to switching back to the Edit Mode
- Navigation bar allows to navigate between different sections of the story
- The **Title** of the story configured in the story settings (edit mode)
- The Logo of the story chosen by the story editor in the story settings

The Story layout allows to navigate contents by scrolling up and down the Story page by using the mouse or the **Navigation bar**.

# Story Settings

The Story Settings panel allows the editor to customize the theme of the story and configure which additional components should appear to end users in the story view.

The Story settings panel is available in Edit Mode and it can be opened by clicking on the **Settings** button

#### Story theme

## Story Theme

The editor can customize the different components of the story through the following sections:

• The **Theme** to choose the default background and text color and the default font of the whole story: clicking on the *Change Color* button *A* a color picker appears to allow selecting the desired color:

• The Font Family to choose the default text font present in the whole story: clicking on the search bar a dropdown menu opens to allow selecting the desired font (Inherit, Arial, Georgia, Impact, Tahoma, Time New Roman, Verdana). The default list of Font Families can be customized in the MapStore configuration file.

• The *Shadow* of overlay *contents* present in the Title Section and in the Immersive Section: to enable or disable the shadow:

• The color of **Links**. The story editor can choose the default color of the hyperlink that may be present in the *Text Contents*.

### Story Header

In the top bar of the story, if the editor enables them, the following components are added:

- The **Title** of the story, the default value is the title given to the story's resource in MapStore.
- The **Font Size** of the title: clicking on the search bar a dropdown menu opens to allow selecting the desired size (*14 px*, *16 px*, *18 px*, *24 px*, *28 px*).
- The story **Logo**, that can be for example an image that represents your organization or something connected to the story itself.
- The **Navigation Toolbar** to improve the story navigation for end users. Each section of the story is reported in a tree and the editor can establish which section should appear in the toolbar to allow end users to quickly navigate the story.

## Title Section

As soon as you create a new Story, by default, only a Title Section (the cover) is present in the workspace. In this section the story editor can customize two different elements: the title text and the cover's background.

### Content

By default, the title section has the following placeholder with an empty background behind it:

With a click inside the text area, it expands and the Text Editor Toolbar appears allowing the story editor to type and/or edit the title text:

Once the text has been written, it is possible to configure the text area position and its style from the component's toolbar:

# List of Highest Astronomical Observatories

The text window toolbar allows the user to change the following settings:

- The **Change size** button allows to change the size of the text window in *Small, Medium, Large* or *Full*.
- The **Align content** button allows to align the text window, inside the Container, on the *Left, Center* or *Right*.
- The **Change field theme** button *in Default* (same default theme settings of the story, see Story Settings), *Bright, Dark* or *Custom* (allows to customize background and text colors and enable or disable the shadow)
- The **Remove** button allows delete the title section.

Setting a title with *Large* size, aligned on the *Center* of the Container and with a *Bright* theme, the result is something like:

## Background

For a Title sections it is possible to customize the background through the background editing toolbar:

In case of an empty background, the background editing toolbar allows to:

- Add a media content as a background, with the **Change media source** button that opens the Media Editor
- Change the height of the section through the Fit/adapt content button

It is possible to add three types of media contents as a background: images, videos or maps.

#### Images

Once an image is added for the background, the result is something like this:

In this case the background editing toolbar allows to customize the image background through the following settings:

- Change media source 🔊 allows to select the media content to use for the section, clicking on this button the Media Editor opens
- Change the content height through the Fit/adapt content button

- Change the relation image/container, choosing between making the background cover the whole container or making the whole background visible inside the container
- Change size 🗴 between Small, Medium, Large or Full
- Align content 🚊 on the Left, Center or Right
- Change the background theme 
  to set the colour of the empty background between Default (same default theme settings of the story, see Story Settings), Bright, Dark or Custom (allows to customize the color of the background).

#### Videos

Once a video is added for the background, the result is something like this:

The background toolbar, in this case, changes a little bit by including an additional button:

• The **Audio**, enabled by default, through which you can enable or mute the video.

By clicking on the *Make the whole background visible inside the container* button other two buttons appear to perform the following operations:

• Enable Autoplay 📀 to play the video automatically once the user is on it

The video play will be available only in View Mode of the story: it is not available in edit mode

• Enable Loop 🔁 to continuously repeat the video

Maps

Note

except in the media editor as a preview.

In this case, adding a map as background, the result will be like this:

The background toolbar, in this case, changes a little bit by including an additional button:

• The **Edit map configuration** through which it is possible to Configure the Map

## **Banner Section**

The Banner Section is similar to the Title Section and it is useful to easily create a story banner without the title text content.

From the background editing toolbar the user can do the following actions:

- Add a media content as a background opening the Media Editor through the Change media source button and choose between images, videos or maps.
- Change the height of the section through the Fit/adapt content button
- Remove the banner section through the **Remove** button

Once the media content has been added as a background of the section, the editing toolbar changes to enable different functionality depending on the content inserted: as explained here.

Below is an example of an image added as background in the Banner Section:

## Paragraph Section

The Paragraph Section allows to insert a textual content to the story. The story editor can also click on the + button to add additional contents to this section (like media, other paragraphs or embed third party contens). It is possible to choose between:

- Text Content **I** to add another text content just below the current one
- Media Content in to open the Media Editor to add an image, a map or a video.
- Web Page Content </>

### Text Content

By default, as soon as a Paragraph is added, an empty text content is already present as a placeholder and the content toolbar allows to:

Insert text here...

+

Change the size of the text content: clicking on the Change Size button
 a dropdown menu appears to allow selecting between Small, Medium or Full size:

This is a list of the highest astronomical o world, considering only ground-based ob

ordered by elevation above mean sea level. The main list includes only permanent observatories with facilities constructed at a fixed location, followed by a supplementary list for temporary observatories such as transportable telescopes or instrument packages. For large observatories with numerous telescopes at a single location, only a single entry is included listing the main elevation of the observatory or of the highest operational instrument if that information is available.insert text here...

MD

Piccola

Media

Grande

+

• Delete the Paragraph Section through the Remove button 👘

The editor can write a text by clicking on the text content and customize it through the Text Editor Toolbar. A possible result of adding and formatting the text can be the following:

This is a list of the **highest astronomical observatories** in the world, considering only ground-based observatories elevation above mean sea level. The main list includes only <u>permanent observatories</u> with facilities constructed at a followed by a supplementary list for <u>temporary observatories</u> such as transportable telescopes or instrument pack observatories with numerous telescopes at a single location, only a single entry is included listing the main elevation of th of the highest operational instrument if that information is available.insert text here...

+

### Media Content

Adding a media content, the Media Editor opens to allow adding the supported media (like Image, Map or Video).

#### Images

An image added inside the paragraph section can be customized through the Image Content Toolbar. Below is an example of a small, center-aligned image, just below a text content:

This is a list of the **highest astronomical observatories** in the world, considering only ground-based observatories a elevation above mean sea level. The main list includes only permanent observatories with facilities constructed at a followed by a supplementary list for temporary observatories such as transportable telescopes or instrument pack observatories with numerous telescopes at a single location, only a single entry is included listing the main el observatory or of the highest operational instrument if that information is available.insert text here...

View showing several of the world's highest observatory sites in Chile. Isoking north across the Liano de Chajnantor and ALMA site, with the peaks of Cerro Toco right center and Cerro Chajnantor right rising above.

#### Videos

A video added inside the paragraph section can be customized through the Video Content Toolbar. Below is an example of a video, just below an image content:

View showing several of the world's highest observatory sites in Chile. looking north across the Llano de Chajnantor and ALMA site, with the peaks of Cerro Toco (right center) and Cerro Chajnantor (right) rising above.

#### Maps

A map added inside the paragraph section can be customized through the Map Content Toolbar. Below is an example of a large, center-aligned map, just below an Image content:

### Web Page Content

Adding a web page content, the Web Page Windows opens allowing the user to add the URL of an extenal web page. A web page added inside the paragraph section can be customized through the Web Page Content Toolbar. Below is an example of a medium, center-aligned web content, just below a map one:

## Immersive Section

The immersive section is composed of two elements: the background and the immersive content. As soon as you add an immersive section to your story, an empty background with an empty text content will be displayed.

### Content

Inside an *Immersive Section* the story editor can customize the content area through the **Immersive Content Toolbar**:

In particular, it possible to:

- The **Change size** button allows to change the size of the text window in *Small, Medium, Large* or *Full.*
- The **Align content** button allows to align the text window, inside the Container, on the *Left, Center* or *Right*.
- The **Change field theme** button *in Default* (same default theme settings of the story, see Story Settings), *Bright, Dark* or *Custom* (allows to customize background and text colors and enable or disable the shadow)

Below is an example of a small Immersive Content, aligned to the *Right* and with a *Dark* field theme:

As soon as you add a text content, it appears available just below the current one. With a simple click inside it, the user can write the text and customize the text formatting through the Text Editor Toolbar. An example of a text content can be the following:

SM 🚊 🖊

The immersive content can include text, media contents or web pages. A new content can be added inside the immersive content column through the + button, or it can be removed through the  $\frac{1}{100}$  button.

MD 🚊 🖋		
Insert text here	🖹 🔤 🚸	
	+	

Adding a media content, the Media Editor appears to allow the story editor to add an Image, a Map or a Video. It is also possible to add a Web Page content as it is explained in the Web Page Section. An example of immersive content with a text and an image can be the following:

#### History of high altitude astronomical observatories

Prior to the late 19th century, almost all astronomical observa throughout history were located at modest elevations, often of cities and educational institutions for the simple reason of convenience.[1] As air pollution from industrialization and light pollution from artificial lighting increased during the Industria Revolution, astronomers sought observatory sites in remote lo with clear and dark skies, naturally drawing them towards the mountains.

## Background

For Immersive sections, it is possible to customize the background through the background editing toolbar:

The background editing toolbar, when no media are applied, allows to:

• Add a media as a background of the section, with the **Change media source** button state opens the Media Editor

Once a media (*image*, *video* or *map*) is added to the background, an editing toolbar appears in the upper left corner of the section allowing the user to manage the background content.

The **Background editing toolbar** changes depending on the type of media added to the background, as it is explained in the Background section.

#### Note

Only for Immersive Section, when the user try to add another section of the same type just below the current one, the added section is actually another immersive content, that fits inside the same immersive section.

## GeoCarousel Section

The GeoCarousel section allows another kind of immersive experience than the Immersive Section. The story editor can define a list of carousel cards to be presented with an accompanying descriptive content and a geographic location. In edit mode it is composed of three elements: the background map, the descriptive panel and the carousel panel where the editor can manage carousel items.

1	Add a background map
E Ta Abstract S	
= <b>₽ 9</b> Geocarousel Section (3) type: carousel

	Geocarousel Preview Not Avaliable
	+ Y

### Background

Batter

The background editing toolbar allows to add a map as a background of the section, with the **Change media source** button  $\overline{\mathbb{N}}$  that opens the Media Editor as usual.

Once a *map* is selected for the background, the editing toolbar appears in the upper left corner of the section allowing the story editor to manage the background content.

The Background editing toolbar allows the following actions:

- Change media source 🔨 allows to select the media content to use for the section, clicking on this button the Media Editor opens.
- The Edit map configuration allows to Configure the Map
- Change size x of the section between Small, Medium, Large or Full
- Align content  $\equiv$  on the Left, Center or Right
- Change the background theme to set the colour of the empty background between *Default* (same default theme settings of the story, see Story Settings), *Bright*, *Dark* or *Custom* (allows to customize the color of the background).

The Align content and the Change field theme buttons are disabled if the map size is full screen.

## Descriptive panel

The Descriptive panel allows to put descriptive content such as *text*, *image*, *video* or *map* for the different cards composing the GeoCarousel section. The story editor can customize it through the **Content Toolbar**, as it is explained in the **Content section**.

### Carousel

The carousel is composed of a list of cards to be associated with a geographic location. It is located at the bottom of the GeoCarousel section and as soon as the section is added to the story, it has by default the following empty card ready to be configured:

Once a card is selected in edit mode, the story editor can perform the following operations through the **Cards editing toolbar**:

• Edit 🔌 the card: clicking on this button the Edit Card panel opens to allow adding *Thumbnail* and *Title*. An example can be the following:

Add new card thumbnail	×
Thumbnail	
Title	
Colorado	
	Add

• Add marker • on map or modify the current marker position: clicking on this button the Map Inline Editor opens, and the story editor can click a point on map to add a new marker or change its position as follows:

In the upper left corner of the Carousel panel, a Carousel toolbar allows to:

-	+ 🗑			
	Geocarousel			
0	Preview Not			
	Avaliable			
	8	0		
00			° 8	

- Add card 🕂 to the carousel
- Remove in the GeoCarousel Section

## GeoCarousel section in View Mode

In a GeoCarousel section, in view Mode, the user can perform the following operations:

• Select a carousel card to view related descriptive content

• Select a *marker* on the map to display its carousel card name popup and view its descriptive content

• Use the left and right arrows < to browse the different geocarousel content

## Media Section

Media Sections are similar to Paragraph Sections but the main difference is that as soon as the story editor try to add a new Media Section, the Media Editor appears, asking to define the media that is going to be added. An example of a new Media Section with an image added can be like the following:

+

Once the first media is added to the Media Section it is possible to add new media, text contents or web page contents or remove the existing ones as decribed also in the Paragraph Sections.

## Web Page Section

Through this kind of sections the story editor can embed third party contents in the story (like other web pages available on the web). The Web Page Section is similar to the Paragraph Section and the Media Section: adding this section a modal window opens to specify the URL of the web page that is going to be added.

L.	
https://en.wikipedia.org/wiki/List_of_highest_astronomical_observate	ories

Below an example of a Web Page Section that embed a Wikipedia site page:

It is possible to add or remove multiple Web Page contents in the same way of text and media contents as it is explained in the Paragraph Sections.

# Text Editor Toolbar

With the *Text Editor Toolbar* it is possible to customize the text by modifying the following aspects:

Font	H1 <b>•</b>	В	Ι	U	<del>5</del>	{}	E	E	Ξ	$\equiv$	1	°	2	)	•
1 Offe	1111		1	<u> </u>	0	63						° —	3		-

- Font to choose the text font (Inherit, Arial, Georgia, Impact, Tahoma, Time New Roman, Verdana)
- **Block Type** by choosing between the available ones (*Normal*, H1, H2, H3, H4, H5, H6, *Blockquote*, *Code*)
- Text style to insert text in Bold  ${f B}$ , Italic  ${\it I}$ , Underline  ${\it U}$  or Strikethrough  ${\it S}$
- Monospace [] to insert the same space between words
- Alignment = inside the text window (Left, Center, Right or Justify)
- Color Picker 🥒 to change the text color
- Bullet list to create a Unordered list  $\cong$  or Ordered list  $\equiv$
- Indent/Outdent \_\_\_\_\_ to indent the text in relation to the left margin or to the right margin
- Link *S* to configure a hyperlink for the selected portion of text. The GeoStory editor can define hyperlinks to external web pages by choosing the *External link* option in the Link target dropdown menu and entering the related URL. As an alternative, it is also possible to define a hyperlink to other sections of the same GeoStory by choosing one of the sections available in the Link target dropdown menu.

Font	•	Normal	•	14	•	в	Ι	U	S	{}	Ξ	Ξ	Ξ	$\equiv$	1	<u>°</u>	IΞ	•==		P	<i>°C</i> ?	۲	
------	---	--------	---	----	---	---	---	---	---	----	---	---	---	----------	---	----------	----	-----	--	---	-------------	---	--

This is a list of the highest astronomical observatories in the world, considering on observatories and ordered by elevation above mean sea level. The main list includ observatories with facilities constructed at a fixed location, followed by a supplem temporary observatories such as transportable telescopes or instrument package observatories with numerous telescopes at a single location, only a single entry is main elevation of the observatory or of the highest operational instrument if that interval able.insert text here...

+

#### Note

In order to setup an hyperlink to an external website, the protocol must be specified (e.g., http:// or https://).

• **Remove** to remove the formatting

# Image Content Toolbar

As soon as an image content is added, the Image Content Toolbar appears on top of the image:

View showing several of the world's highest observatory sites in Chile, looking north across the Llano de Chajna ALMA site, with the peaks of Cerro Toco (right center) and Cerro Chajnantor (right) rising above.

+

Through this toolbar, the story editor is able to perform the following operation:

- Change media source 🔌 accessing the Media Editor
- Change size LG choosing between Small, Medium, Large

- **Hide caption** button button is present only if a description has been provided for the image resource (see the Media Editor tool for example)
- $\cdot$  **Remove**  $\widehat{\mathbf{m}}$  the image content

# Video Content Toolbar

As soon as a video content is added, the Video Content Toolbar appears on top of the video:

The Best Stargazing is at the Northern Tip of India

+

Through this toolbar, the story editor is able to perform the following operation:

- Change media source 🔌 to open the Media Editor and change (or configure) the media content
- Mute video 🔊 to disable the video audio
- Enable Autoplay 🕟 to play the video automatically once the user is on it
- Enable Loop 🔁 to continuously repeat the video

- **Hide caption** button button is present only if a description has been provided for the video resource (see the Media Editor tool for example)
- Remove 🝿 the video content

#### Note

Inside the Media Editor you can watch a preview of the video before adding it to the story. The video play will be available only in *View Mode* of the story: it is not available in edit mode except in the media editor as a preview.

# Map Content Toolbar

As soon as a map content is added, the Map Content Toolbar appears on top of the map component:

In particular, through this toolbar, the story editor is able to perform the following operation:

- Change media source 🔌 accessing the Media Editor
- Edit map configuration 🔐 through which it is possible Configure the map
- Change size LG choosing between Small, Medium, Large

- **Hide caption** button button is present only if a description has been provided for the map resource (see the Media Editor tool for example)
- $\cdot$  **Remove**  $\overline{m}$  the map content

# Web Page Content Toolbar

As soon as a Web Page Content is added, the toolbar appears on top of the content itself:

+

In particular, through this toolbar, the editor is able to perform the following operation:

- Change horizontal size ↔ choosing between Small, Medium, Large and Full
- Edit web page URL 🔌 accessing the web page windows to change the web URL

**Change vertical size** (choosing between *Small, Medium, Large* 

 $\cdot$  **Remove**  $\overline{\mathbf{m}}$  the Web Page content

# Media Editor Window

The **Change media source** button 🔨 allows to access the Media Editor:

Through this window, you can add or edit three different types of media:

- Images
- Videos
- Maps

#### Images

In order to add an image, the stroy editor can click on the **Images** tab **Images** in order to switch to the images section. In this section of the media editor window, with a click on the **Add** button +, it is possible to define the image settings.

Media
Images Videos Maps
← 🕒
Source
https://demo.geo-solutions.it/mockups/
Title
Indian
Alternative text
Enter an alternative text
Description
The Indian Astronomical Observatory star
Credits
Enter credits

In particular, it is possible to insert the following parameters:

- The **Source** of the image (its URL)
- The Title of the image
- The Alternative text, that appears if the link is broken
- A **Description**, used to explain the contents of the image. The description is available in the images preview list and, if the image is added as content in the *Pharagraph section*, in the *Immersive section* or in the *Media section*, under the image, as follows:

• The Credits, displayed on the bottom-right of the image

With a click on **Save**, the image is included in the list of the available images ready to be selected for the current story. The image also becomes immediately available on preview.

It is always possible to change the image settings through the <b>Edit</b> button 💉 also in a	note	
second time.		also in a

Once selectd in the list, the image can be included in the story by clicking on the **Apply** button Apply.

### Videos

In order to add a video, the stroy editor can click on the **Video** tab **Videos** in order to switch to the videos section. In this section of the media editor window, with a click on the **Add** button +, it is possible to define the video settings.

In particular, it is possible to insert the following parameters:

- The URL of the video
- The Title of the video
- A **Description**, used to explain the contents of the video. The description is available in the viedos preview list and it can appear under the video itself if the video is added as a content of a section (*Pharagraph section*, *Immersive section* or *Media section*)
- The Credits, displayed on the bottom-right of the video

Video URL and Title are mandatory fields.

With a click on **Save**, the video is included in the list of the available videos ready to be selected for the current story. The video also becomes immediately available on preview.

Once selectd in the list, the video can be included in the story by clicking on the **Apply** button Apply.

#### Maps

To add a map to the story, the story editor can click on the **Maps** tab Maps and so swich to the map section of the Media Editor. Here the list of maps ready to be used for the story is available: the editor can search and select a map in the list to apply it in the story or create a map from scratch by clicking on the **Add** button + to open the Map Editor.

Once the map is ready, the story editor can click on **Ok** button **ok** to proceed with the next step and therefore insert the related map metadata like **Thumbnail**, **Title** and **Description**.

The description is available in the maps preview list and it can appear under the map itself if the map is added as a content of a section (*Pharagraph section*, *Immersive section* or *Media section*).

With a click on **Save** button 💾 the map is saved and it will be available in the

list of the *Current Story* maps. The story editor can select it to be used as a map component in the story by clicking on **Apply** button Apply.

Note

By default a drop down list on the top right corner of the Media Editor allows to switch between maps currently used in the story (so the story editor can use again a map already present in the story if needed) and existing maps already available inside the MapStore catalog (that means that also classic maps created in MapStore can be used inside a Story).

nages Maps

ded 10 of 266 matched	

Below is an example of a *Map* used as a background of a Title Section:

# Configure the map

With the Edit map configuration button if the **Map Inline Editor** opens to give the opportunity to do quick customizations (like basic map settings, layer opacity and something more) to the map (more advanced customizations then, are allowed only through the *Advanced Map Editor*).

### Layers

The Map Inline Editor opens with the Layers section available, where it is possible to edit the layers settings (by selecting a layer in the TOC) and the visibility of layers present in the map:

- Control the layer transparency by scrolling left and right the transparency bar
- $\cdot$  Toggle the layer visibility by switching off  $\not$  and on o the "eye" icon.

## Setting

The Setting section allows the user to:

- Enable/disable the Zoom in/out on the map
- Change the position of the **Zoom in/out** by choosing one of the options available in the dropdown menu

- ${\boldsymbol{\cdot}}$  Enable/disable the  ${\textbf{Pan}}$  interaction on the map
- Enable/disable the **Identify** on the map. As reported in the Identify tool section, also for map sections in a story it is possible to enable the *Identify tool* in one of the format supported by MapStore (*TEXT*, *HTML* or *PROPERTIES*)

#### Note

The Identify request is performed as usual when the user clicks on a layer in the map, as follows:

## Advanced map editor

Inside the Map Inline Editor Toolbar the **Advanced map editor** button sis also available to allow advanced customization to the map: clicking on that button, a MapStore viewer opens for this purpose.

The available tools to modify the map are the following:

- Adding the Layers by using the CATALOG button in the Option menu as it is explained in the Catalog Services.
- Adding **Annotations** by clicking on the parameters button in the *Option menu* as it is explained in the Adding Annotations.
- Import a map or a vectorial file by clicking on the 
  IMPORT button in the Option menu = as it is explained in the Import files.
- Change Background as it is explained in the Background Selector
- Edit Layers by clicking on the Layers button s as it is explained in the Table of Contents

Once the advanced map editing is complete, it is possible click on **Apply** to see the final result in the story.

# Requirements

In this section you can have a glance of the minimum and recommended versions of the tools needed to build/debug/install MapStore

## War Installation

You can download a java web container like Apache Tomcat from and Java JRE

Tool	Link	Minimum	Recommended	Maximum
Java	link	8	9	111
Tomcat	link	8.5	9	91

## Debug / Build

These tools needs to be installed (other than Java in versions above above):

Tool	Link	Minimum	Recommended	Maximum
npm	link	5	6	6.14.13 <sup>2</sup>
NodeJS	link	10	12	14.17.0 <sup>2</sup>
Java (JDK)	link	8	9	111
Maven	link	3.1.0	3.6	
python <sup>3</sup>	link	2.7.9	3.7	

#### Notes

Here some notes about some requirements and reasons for max version indicated, for future improvements and maintenance :

- <sup>1</sup> About Java and Tomcat
  - For execution tested on Java v11.
  - Build with success with v11, only smoke tests passing on v13, errors with v16.(Details on issue #6935)
  - Running with Tomcat 10 causes this issue #7524.
- <sup>2</sup> About NodeJS and NPM:
  - NPM 7 not supported yet.
  - NPM 6.14.15 causes this issue on MapStore project system. No other know issues.
  - If you are using Node >= 12 you can remove the -max\_old\_space\_size=2048 config for the compile script
- <sup>3</sup> Python is only needed for building documentation.

#### Running in Production

#### System requirements

Resource	Minimum	Recommended
Processor	2 Core	2 Core
Memory	2 GB	4 GB

#### Database

In production a PostgreSQL database is recommended:

Tool	Link	Minimum	Recommended	Maximum
Postgres	link	9.6	13	13

# Quick Setup and Run

Note

Please make sure to have installed all the software as for requirements before to proceed.

#### Clone the repository:

git clone https://github.com/geosolutions-it/MapStore2.git

#### Start the demo locally:

npm cache clean # this is useful to prevent errors on Windows
during install

npm install

npm start

Then point your preferred browser to http://localhost:8081.

This application runs the Java backend at localhost:8080. Make sure to have both ports 8080 and 8081 free before to run.

### Other useful commands

```
# Run tests
npm test
# run test with hot reload
npm run test:watch
```

#generate test documentation
npm run doc:test

### Quick Build and Deploy

Install latest Maven, if needed, from here (version 3.1.0 is required).

Build the deployable war:

```
./build.sh [version_identifier]
```

Where version\_identifier is an optional identifier of the generated war that will be shown in the settings panel of the application.

Deploy the generated mapstore.war file (in product/target) to your favourite J2EE container (e.g. Tomcat).

Here you can find how to setup the database.

# Main scripts

Here a summary of the main utility scripts to run and build MapStore.

npm scripts

Command	Description
npm install	download dependencies and init the front-end environment
npm start	start development instance (both front end and back-end)
npm run app:start	start development instance (both front end and back-end)
npm run fe:start	start front-end dev server
npm run be:start	start backend dev server (embedded in tomcat, with cargo)
npm run fe:build	build front-end
npm run be:build	build backend
npm test	run test suite once
npm run test:watch	run continuous test suite running (useful during developing)
npm run lint	run ESLint checks
npm run i18n	checks missing strings in mandatory i18n files (ref to en-US)
npm run jsdoc:build	build JSDoc
npm run jsdoc:test	build JSDoc in a directory available running npm start (for test)
npm run jsdoc:clean	clean JSDoc
npm run doc:build	build MkDocs documentation
npm run doc:start	start mkdocs serve to have a live preview while editing documentation
npm run generate:icons	generate icons from svg files
npm run generate:changelog	generate changelog for the MapStore release

Other scripts are present for backward compatibility, but they are deprecated and will be removed in the future.

## bash scripts

Command	Description
./build.sh [version_identifier]	build the deployable war (in product/
[profiles]	target )

Where version\_identifier is an optional identifier of the generated war that will be shown in the settings panel of the application and profiles is an optional list of comma delimited building profiles (e.g. printing, ldap).

# Infrastructure

MapStore leverages a full separation of concerns between the **backend** and the **frontend**.

The frontend is a Javascript web application communicating with MapStore own web services using AJAX and external ones through an internal, configurable, *proxy*.

The backend is a suite of web services, developed in Java and deployed into a J2EE container (e.g. Apache Tomcat).

### Frontend

The frontend is based on the ReactJS library and the Redux architecture, which is a specific implementation of the Flux architecture.

It allows plugging different mapping libraries (with **Leaflet** and **OpenLayers** as our first implementation targets) abstracting libraries implementation details using ReactJS *web components* and *actions based communication*.

## Backend

Backend services include at least (but not only) these ones:

- Generic, configurable, **HTTP-Proxy** to avoid CORS issues when the frontend tries to communicate with external services, based on the GeoSolutions http-proxy project.
- Internal **storage** for non structured resources (json, XML, etc.) based on the GeoSolutions GeoStore project.

- **Configuration** services, to allow full application(s) and services configurability
- **Security** with the ability to configure authentication using an internal or external service, and a flexible authorization policy for services and resources access.

# Developing with MapStore

MapStore is both an application and a framework. This guide is both for developers who want to extend MapStore and for those who want to create their custom application using MapStore as a framework.

# MapStore as an application

MapStore is 99% client side, and uses some Java back-end services

Back-end mainly consists in services included from external projects (GeoStore, MapFish Print, HTTP-Proxy...) plus some small service owned by MapStore, all written in Java.

Developing with MapStore as an application means to develop directly on the project. You can add plugins or improve the existing code base and, hopefully, send pull requests on GitHub to include your improvements in the main project.

# MapStore as a Framework

The recommended way to use MapStore as a framework is to create a project that includes MapStore as a sub-folder. For this purpose we created a script that generates the main folder structure and the necessary files Project Creation Script.

This setup allows to create your application or customizations inside the js directory and/or add custom back-end services (the set-up allows to create a project that builds a Java WAR package). Keeping your customization separated and MapStore as a git sub-modules has the followind advantages:

- $\cdot$  Clear separation between the framework and your customization
- Easy framework update: updating the git sub-module.
- Easy customization of MapStore: You can fork the project, if you need hard customization. If your customization can be included in MapStore, you can

do a pull request to the main project and work on a branch while waiting the pull request merge.

# Folders structure

This is the overall framework folder structure:

```
+-- package.json
+-- pom.xml
+-- build.sh
+-- .editorconfia
+-- Dockerfile
+-- ...
+-- build (build related files)
   +-- karma.conf.*.js
   +-- tests.webpack.js
   +-- webpack.config.js
   +-- prod-webpack.config.js
   +-- docma-config.json
   +-- testConfig.json
   +-- ...
+-- java
              (java backend modules)
   +-- pom.xml
   +-- services
   +-- web
   +-- printing
+-- translations (i18n localization files)
    | +-- data.en-US.json
+-- utility (general utility scripts and functions)
    | +-- eslint
    | +-- build
    +-- projects
   +-- translations
+-- web
              (frontend module)
   +-- client
       +-- index.html (demo application home page)
    +-- plugins (ReactJS smart components with required
reducers)
       +-- components (ReactJS dumb components)
          +-- category
           +-- <component>.jsx (ReactJS component)
           +-- ...
           +-- __tests__ (unit tests folder)
        +-- <component>-test.jsx
           +-- ...
       +-- actions (Redux actions)
+-- configs (JSON config files like
```

```
localConfig.json, pluginsConfig.json, new.json,
newgeostory.json, etc)
+-- epics (redux-observable epics)
+-- reducers (Redux reducers)
+-- stores (Redux stores)
...
product (the MapStore main application)
+...
```

# Developing with MapStore

Due to the dual nature of the project (Java backend and JavaScript frontend) building and developing using the MapStore framework requires two distinct set of tools

- Apache Maven for Java
- NPM for JavaScript.

A basic knowledge of both tools is required.

## Start developing

To start developing the MapStore framework you have to:

· download developer tools and install frontend dependencies locally:

npm install

After a while (depending on the network bandwidth) the full set of dependencies and tools will be downloaded to the **node\_modules** sub-folder.

• start the local dev server instances with:

npm start

Then point your preferred browser to http://localhost:8081/?debug=true#/. By default the frontend works using the local dev server as backend. This configuration is suggested if you want to develop.

Note

npm start will run both front-end on port 8081 and back-end on port 8080 (make sure to have both the ports available). The first time back-end will take a lot to start, downloading all the dependencies.

If you still want to start only the frontend because you have the backend running in a tomcat container for example you may simply run

npm start

See the dedicated section in this page for more info

## Frontend

You can run only the front-end running npm run fe:start . Running this script MapStore will run on port 8081 and will look for the back-end at port 8080 .

If you want to use an online instance of MapStore as backend, instead of the local one, you can define the environment variable MAPSTORE\_BACKEND\_URL to the desired URL.

#### Debugging

The development instance uses file watching and live reload, so each time a MapStore file is changed, the browser will reload the updated application.

Use your favorite editor / IDE to develop and debug on the browser as needed.

We suggest to use one of the following:

- Visual Studio Code with the following plugins:
- ESLint dbaeumer.vscode-eslint
- EditorConfig for VSCode editorconfig.editorconfig
- Atom with the following plugins:
- editorconfig
- linter
- linter-eslint
- react
- Icovinfo
- minimap & minimap-highlight-selected
- highlight-line & highlight-selected
- Sublime Text Editor with the following plugins:
- Babel
- Babel snippets
- Emmet

#### **Redux Dev Tools**

When you are running the application locally using <u>npm start</u> you can debug the application with redux dev tools using the flag ?debug=true

http://localhost:8081/?debug=true#/

It also integrates with the browser's extension, if installed.

This way you can monitor the application's state evolution and the action triggered by your application.

#### Unit tests

To run the MapStore frontend test suite you can use:

npm test

You can also have a continuously running watching test runner, that will execute the complete suite each time a file is changed, launching:

npm run test:watch

Usually during the development you may need to execute less tests, when working on some specific files.

You can reduce the tests invoked in npm run test:watch execution by editing the file tests.webpack.js and modifying the directory (/web) and/or the regular expression that intercept the files to execute.

To run ESLint checks launch:

npm run lint

More information on frontend building tools and configuration is available here

## Backend

In order to have a full running MapStore in development environment, you need to run also the backend java part locally. This runs automatically with <code>npm start</code>. If you want to run only the backend, you can use <code>npm run be:start</code>.

The back end will run on port 8080 and will look for the front-end at port 8081. If you want to change the back-end port, you can set the environment variable MAPSTORE\_BACKEND\_PORT to the desired port.

```
export MAPSTORE_BACKEND_PORT=8082
npm start # or npm run be:start
```

#### Defaults Users and Database

Running MapStore backend locally, on start-up you will find the following users:

- admin , with ADMIN role and password admin
- user with USER role with password user

You can login as admin to set-up new users and access to all the features reserved to ADMIN users.

The database used by default in this mode is H2 on disk. You can find the files of the database in the directory webapps/mapstore/ starting from your execution context. Check how to set-up database in the dedicated section of the documentation.

#### **Running Backend**

When we say "running the backend", in fact we say that we are running some sort of a whole instance of MapStore locally, that can be used as backend for your frontend dev server, or for debugging of the backend itself.

#### **Embedded tomcat**

MapStore is configured to use a maven plugin-in to build and run mapstore locally in tomcat. To use it you have to:

• npm run be:start

Now you are good to go, and you can start the frontend

Your local backend will now start at http://localhost:8080/mapstore/. If you want to change the port you can edit the dedicated entry in product/pom.xml, just remember to change also the dev-server proxy configuration on the frontend in the same way.

#### Local tomcat instance

If you prefer, or if you have some problems with mvn cargo:run, you can run MapStore backend in a tomcat instance instead of using the embedded one. To do so, you can :

- download a tomcat standalone here and extract to a folder of your choice
- To generate a war file that will be deployed on your tomcat server, go to the root of the Mapstore project that was git cloned and run ./build.sh. This might take some time but at the end a war file named mapstore.war will be generated into the product/target folder.
- Copy the mapstore.war and then head back to your tomcat folder. Look for a webapps folder and paste the mapstore.war file there.
- To start tomcat server, go to the terminal, cd into the root of your tomcat extracted folder and run ./bin/startup.sh (unix systems) or ./bin/ startup.bat (Windows). The server will start on port 8080 and Mapstore will be running at http://localhost:8080/mapstore. For development purposes we're only interested in the backend that was started on the tomcat server along with Mapstore.

Even in this case you can connect your frontend to point to this instance of MapStore.

#### Debug

To run or debug the server side part of MapStore we suggest to run the backend in tomcat (embedded or installed) and connect in remote debugging to it. This guide explains how to do it with Eclipse. This procedure has been tested with Eclipse Luna.

#### Enable Remote Debugging

for embedded tomcat you can configure the following:

```
# Linux
export MAVEN_OPTS="-Xdebug -Xnoagent -Djava.compiler=NONE -
Xrunjdwp:transport=dt_socket,address=4000,server=y,suspend=n"
```

```
# Windows
set MAVEN_OPTS=-Xdebug -Xnoagent -Djava.compiler=NONE -
Xrunjdwp:transport=dt_socket,address=4000,server=y,suspend=n
```

#### then start tomcat

```
npm start # or npm run start:app, or npm run be:start (this
last only for the backend)
```

For your local tomcat, you can follow the standard procedure to debug with tomcat.

#### Setup eclipse project

Run eclipse plugin

mvn eclipse:eclipse

- Import the project in eclipse from File --> Import
- Then select Existing project into the Workspace
- Select root directory as MapStore root (to avoid eclipse to iterate over all node\_modules directories looking for eclipse project)
- import all projects

#### Start Debugging with eclipse

- Start Eclipse and open Run --> Debug Configurations
- Create a new Remote Java Application selecting the project "mapstoreproduct" setting:

- host localhost
- port 4000
- Click on *Debug* Remote debugging is now available.

**NOTE** With some version of eclipse you will have to set suspend=y in mvn options to make it work. In this case the server will wait for the debug connection at port 4000 (address=4000)

# Building and deploying

To create the final war, you have several options:

 full build (including all tests, syntax checks, frontend, backend and documentation):

```
./build.sh [version_identifier] [profiles]
```

Where version\_identifier is an optional identifier of the generated war that will be shown in the settings panel of the application and profiles is an optional list of comma delimited building profiles (e.g. printing, ldap, binary)

• separated builds (skipping all the tests and checks, mainly for development purposes):

```bin sh

# build the front-end

#### npm run fe:build

# build the back-end, including the front-end parts build in the previous command

mvn clean install -Dmapstore2.version=[version\_identifier] [profiles]

In this case we have 2 separated commands that can be run separately, for instance if you are working on back-end only, so you don't need to re-compile the front-end part every time. ## Building the documentation MapStore generates 2 types of documentation: \* JSDoc: generated from source code, provides a reference of

```
the API and for the plugins configurations
* MkDocs: generated from markdown files, provides guides for
the developers and users
### API and Plugins documentation (JSDoc)
The API and plugins documentation is automatically generated
using [docma](http://onury.github.io/docma/). Docma
parses the JSDoc comments in the source code and generates a
static HTML documentation.
Refer to the existing files to follow the documentation style
of various parts of the application:
* [actions](https://github.com/geosolutions-it/MapStore2/blob/
master/web/client/actions/controls.js)
* [reducers](https://github.com/geosolutions-it/MapStore2/blob/
master/web/client/reducers/controls.js)
* [components](https://github.com/geosolutions-it/MapStore2/
blob/master/web/client/components/buttons/FullScreenButton.jsx)
* [epics](https://github.com/geosolutions-it/MapStore2/blob/
master/web/client/epics/fullscreen.js)
* [plugins](https://github.com/geosolutions-it/MapStore2/blob/
master/web/client/plugins/Login.jsx)
Please see [http://usejsdoc.org/](http://usejsdoc.org/) for
further information about how to write proper documentation in
JSDoc.
To install docma:
`npm install -g docma`
While developing you can generate the documentation to be
accessible in the local machine by:
`npm run jsdoc:test`
The resulting doc will be accessible from [http://localhost:
8081/mapstore/docs/](http://localhost:8081/mapstore/docs/)
For the production deploy a different npm task must be used:
`npm run jsdoc:build`
The documentation will be accessible from the */mapstore/docs/*
path
```

The generated folders can be removed with:

`npm run jsdoc:clean` ### Users and developers documentation (MkDocs) !!! Note Make sure to install the proper python dependencies for Mkdocs. See the dedicated page [here](./documentationguidelines.md#building-documentation) Build the mkdocs and generate md files to test in local machine by: `npm run doc:build` Start the built-in dev-server of mkdocs to preview and test documentation live by: `npm run doc:start` ## Understanding frontend building tools Frontend building is delegated to [NPM](https://www.npmjs.com/) and so leverages the NodeJS ecosystem. In particular: \* a \*\*[package.json](https://github.com/geosolutions-it/ MapStore2/blob/master/package.json)\*\* file is used to configure frontend dependencies, needed tools and building scripts \* \*\*[babel](https://babeljs.io/)\*\* is used for ES6/7 and JSX transpiling integrated with the other tools (e.g. webpack) \* \*\*[webpack-dev-server](http://webpack.github.io/docs/webpackdev-server.html)\*\* is used to host the development application instance \* \*\*[mocha](http://mochajs.org/)/[expect](https://github.com/ mjackson/expect)\*\* is used as a testing framework (with BDD style unit-tests) \* \*\*[webpack](http://webpack.github.io/)\*\*: as the bundling tool, for development (see [webpack.config.js](https:// github.com/geosolutions-it/MapStore2/blob/master/build/ webpack.config.js)), deploy (see [prod-webpack.config.js] (https://github.com/geosolutions-it/MapStore2/blob/master/build/ prod-webpack.config.js)) and test (see [test.webpack.js] (https://github.com/geosolutions-it/MapStore2/blob/master/build/ tests.webpack.js)) \* \*\*[karma](http://karma-runner.github.io/)\*\* is used as the test suite runner, with several plugins to allow for custom

```
reporting, browser running and so on; the test suite running is
configured through different configuration files, for **[single
running](https://github.com/geosolutions-it/MapStore2/blob/
master/build/karma.conf.single-run.js)** or **[continuous
testing](https://github.com/geosolutions-it/MapStore2/blob/
master/build/karma.conf.continuous-test.js)**
* **[istanbul](https://gotwarlost.github.io/istanbul/)/
[coveralls](https://www.npmjs.com/package/coveralls)** are used
for code coverage reporting
## Including the printing engine in your build
The [printing module](printing-module.md#printing-module) is
not included in official builds by default.
To build your own version of MapStore with the this module, you
can use the **printing** profile running the build script:
```sh
./build.sh [version_identifier] printing
```

For more information or troubleshooting about the printing module you can see the dedicated section

# Main Frontend Technologies

The main tecnologies used on the mapstore 2 are:

- ReactJS (View)
- Redux (state management)

## ReactJS

ReactJS 0.16.x is used to develop MapStore. The main purpose of ReactJS is to allow writing the **View** of the application, through the composition of *small components*, in a *declarative way*.

Components are written using a "templating" language, called **JSX**, that is a sort of composition of HTML and Javascript code. The difference between JSX and older approaches like *JSP* is that JSX templates are mixed with Javascript code inside javascript files.

#### ReactJS component example

Component definition:

```
class MyComponent extends React.Component {
    render() {
        return <h1>{this.props.title}</h1>;
    }
}
```

Component usage:

React.render(<MyComponent title="My title"/>, document.body);

### Properties, State and Event handlers

Components can define and use **properties**, like the title one used in the example. These are immutable, and cannot be changed by component's code.

Components can also use **state** that can change. When the state changes, the component is updated (re-rendered) automatically.

```
class MyComponent extends React.Component {
  state = {
     return {
        title: 'CHANGE_ME'
     };
  };
  changeTitle = () => {
     this.setState({
       title: 'CHANGED'
     });
  };
  render() {
      return <h1 onClick={this.changeTitle}>{this.state.title}
</h1>;
  }
}
```

In this example, the initial state includes a title property whose value is CHANGE\_ME .

When the h1 element is clicked, the state is changed so that title becomes CHANGED .

The HTML page is automatically updated by ReactJS, each time the state changes (each time this.setState is called). For this reason we say that JSX allows to declaratively describe the View for each possible application state.

## Lifecycle hooks

Components can re-define some lifecycle methods, to execute actions in certain moments of the component life. Lifecycle API is changed in react 16 so please refer to the official documentation.

## Redux

Redux, and its companion react-redux are used to handle the application state and bind it to ReactJS components.

Redux promotes a unidirectional dataflow (inspired by the Flux architecture) and immutable state transformation using reducers, to achieve predictable and reproducable application behaviour.

A single, global, **Store** is delegated to contain all the application state.

The state can be changed dispatching **Actions** to the store.

Each action produces a new state (the state is never changed, a new state is produced and that is the new application state), through the usage of one or more **reducers**.

(Smart) Components can be connected to the store and be notified when the state changes, so that views are automatically updated.

#### Actions

In Redux, actions are actions descriptors, generated by an action creator. Actions descriptors are usually defined by an **action type** and a set of parameters that specify the action payload.

```
const CHANGE_TITLE= 'CHANGE_TITLE';
// action creator
function changeTitle(newTitle) {
    return {
        type: CHANGE_TITLE,
        title: newTitle
    };
}
```

#### Reducers

Reducers are functions that receive an action and the current state and:

- produce a new state, for each recognized action
- produce the current state for unrecognized actions
- · produce initial state, if the current state is undefined

```
function reducer(state = {title: "CHANGE_ME"}, action) {
    switch (action.type) {
        case CHANGE_TITLE:
            return {title: action.title};
        default:
            return state;
    }
}
```

#### Store

The redux store combines different reducers to produce a global state, with a slice for each used reducer.

```
var rootReducer = combineReducers({
    slice1: reducer1,
    slice2: reducer2
});
var initialState = {slice1: {}, slice2: {}};
var store = createStore(rootReducer, initialState);
```

The Redux store receives actions, through a dispatch method, and creates a new application state, using the configured reducers.

store.dispatch(changeTitle('New title'));

You can subscribe to the store, to be notified whenever the state changes.

store.subscribe(function handleChange() {});

#### **Redux Middlewares**

Redux data flow is synchronous. To provide asynchronous functionalities (e.g. Ajax) redux needs a middleware. Actually MapStore uses 2 middlewares for this purpose:

- Redux thunk (going to be fully replaced by redux-observable)
- Redux Observable

#### **Redux thunk**

This middleware allows to perform simple asynchronous flows by returning a function from the action creator (instead of a action object).

```
// action creator
function changeTitleAsync() {
    return (dispatch, getState) => {
        myAsyncPromise.then( (newTitle) => {
            dispatch({
               type: CHANGE_TITLE,
               title: newTitle
            };)
        });
    }
}
```

This middleware is there from the beginning of the MapStore history. During the years, some better middlewares have been developed for this purpose. We want to replace it in the future with redux-observable.

#### **Redux Observable and epics**

This middleware provides support for side-effects in MapStore using rxjs. The core object of this middleware is the epic

```
function (action$: Observable<Action>, store: Store):
Observable<Action>;
```

The epic is a function that simply gets as first parameter an Observable (stream) emitting the actions emitted by redux. It returns another Observable (stream) that emits actions that will be forwarded to redux too.

So there are 2 streams:

- Actions in
- Actions out

A simple epic example can be the following:

```
const pingEpic = action$ =>
  action$.filter(action => action.type === 'PING')
  .mapTo({ type: 'PONG' });
```

Every time a 'PING' action is emitted, the epic will emit also the 'PONG' action.

See :

- Introduction to RxJS for MapStore Developers
- redux-observable site
- rxjs Observable as a reference for methods
- setting up the middleware to integrate epics with your store

## Redux and ReactJS integration

The **react-redux** library can be used to connect the Redux application state to ReactJS components.

This can be done in the following way:

• wrap the ReactJS root component with the react-redux **Provider** component, to bind the Redux store to the ReactJS view

```
React.render(
    <Provider store={store}>
      {() => <App />}
    </Provider>,
    document.getElementById('container')
);
```

• explicitly connect one or more (smart) components to a all or part of the state (you can also transform the state and have computed properties)

```
connect(function(state) {
    return {
        title: state.title,
        name: state.namespace + '.' + state.name,
    };
})(App);
```

The connected component will get automatic access to the configured slice through properties:

```
function render() {
    return <div><h1>{this.props.title}</h1>{this.props.name}</div);
}</pre>
```

# Plugins Architecture

The architecture of MapStore based on the concept of **plugins**. Every tool of MapStore is a plugin, that are the main building blocks of the application.

A plugin in MapStore an entity that can be:

- rendered in the application (via a React components)
- **connected** to a Redux store, so that some properties are automatically wired to the standard MapStore state
- wired to standard actions for common events to trigger

In addition a plugin:

- declares some reducers that adds some parts to the global state, if needed
- declares some epics that need to be added to the redux-observable middleare, if needed
- inject in other plugin react components to be rendered (for communication, extensions, etc.)
- is fully **configurable** to be easily customized to a certain level

The plugins are managed by PluginContainer (typically a Page, but not necessarily) that is a React component that renders the plugins in the application and handle proper dependencies.

Plugins are used in different contexts:

- **Standard plugins** Plugins that are used in the standard MapStore application and that are part of the framework.
- **Custom plugins** Plugins developed in a custom MapStore project ( see Setup a MapStore Project)
- Extensions: Plugins that can be build and installed in an existing instance of MapStore (see Extensions)

For more information about how to create a plugin, see Create your plugins

# Internationalization

MapStore offers the support for internationalization (I18N). To provide this functionality MapStore uses react-intl. In this section you can find which configuration and JS files are involved in the I18N system.

## How MapStore chooses the current language

MapStore first checks the browser's language. If it is not supported, MapStore will be visible in english, if present, or the first language available. Anyway the locale can be forced using a flag locale=codeLang where codeLang can be one en,it,de... e.g.

```
localhost:8081/?locale=en#/
```

A user can change the selected language from UI. MapStore will load the proper files to update the page localized in the selected language.

# Configuration files

To provide support to a specific language MapStore need to have the necessary setup in the LocaleUtils.js file (see below [section for details about to configure this file]). In addition you need the proper translations files.

Let's imagine that the variable code is 'en', CODE is 'EN' standing for english. For each language you need to have **messages file** containing the localized strings, a **flag image** to identify the language and some **html fragments** (optional) for some specific plugins.

- Messages: located in web\client\translations folder. For each language there is a json file named data.code-CODE.json. e.g. data.en-EN.json.
- Flags: located in web\client\components\I18N\images\flags folder. For each language flag image named code-CODE.png of 16px x 11px is required.

• Fragments: actually only for cookies policy .... (required only if the Cookie plugin is present) located in web\client\translations\fragments\cookie folder and named cookieDetails-code-CODE.html. We recommend to add it for any language you want to support at least by copying the english version.

# How to configure supported languages in MapStore

You can configure MapStore to provide to the user only a restricted list of selectable languages by setting "initialState.defaultState.locales" variable in localConfig.json.e.g:

Setting locales in localConfig.json file is doable only for supported locales present in LocaleUtils.js. The default behavior is to use those already configured in "supportedLocales" object. You can customize the messages by editing the data.code-CODE.json files.

The locale property determines the language to use for the application. If not specified, the language will be selected checking the browser's locale first. If the browser locale is not supported, MapStore will select the first language available in supportedLocales.

Example of localConfig.json with the optional locale property.

```
{
    "locale": "it-IT", // locale code
    "defaultState": {
        "locales": {
            "supportedLocales": {
                "en": {
                    "code": "en-US",
                    "description": "English"
                },
                "it": {
                    "code": "it-IT",
                    "description": "Italiano"
                }
            }
       }
   }
}
```

The property locale could be useful inside custom application where the locale is stored in other sources rather than using the browser language:

```
// example
import { getConfigProp } from '@mapstore/framework/utils/
ConfigUtils';
import cookies from 'js-cookie';
// ...
const locale = cookies.get('app_locale'); // locale code it-IT
for example
if (locale) {
   setConfigProp('locale', locale);
}
// ...
```

# How to add a new language

Let's say we want to add the russian language. In order to add a new language to MapStore you need to follow these steps:

• Update the localConfig.json file in web\client folder adding the new language entry: Add the following in the initialState.defaultState.locales object

```
"ru": {
    code: "ru-RU",
    description: "Российский"
}
```

 Update the LocaleUtils.js file in web\client\utils: add a param in the ensureIntl() function like and the relative require i.e: 'intl/locale-data/ jsonp/ru.js'

require('intl/locale-data/jsonp/ru.js');

• update the addLocaleData() call with the new locale obj i.e.:

```
const ru = require('react-intl/locale-data/ru');
addLocaleData([...en, ...it, ...fr, ...de, ...es, ...ru]);
```

- add the flag image for the selected language inside
   web\client\components\I18N\images\flags naming it ru-RU.png
- add the new translations file inside web\client\translations naming it data.ru-RU.json (remember to change the locale property of this file into ru-RU)
- create a fragment related to the cookie module inside web\client\translations\fragments\cookie naming it cookieDetailsru-RU.html

# Custom Dependencies

Mapstore has some custom dependencies in order to fix bugs not integrated in the official libraries yet. All these customized libraries are available on npm registry.

Here is a list of customizations:

library	version	issue	reason	github
wkt- parser	1.2.1	#2175	Fixes axis order recognition. For this reason we customized it with "@geosolutions@wkt-parser 1.2.2"	https:// github.com/ geosolutions-it/ wkt-parser/ tree/release
proj4	2.4.5- alpha	#2175	Fixes axis order recognition. For this reason we customized it with "@geosolutions@proj4 2.4.6" and its wkt-parser dependency with "@geosolutions@wkt-parser 1.2.2". Note that shpjs will use this customized version of proj4 and wkt-parser	https:// github.com/ geosolutions-it/ proj4js/tree/ release_2.4.6
react- joyride	1.10.1		is a re-publish on npm of a fix made here , we therefore are using "@geosolutions@react- joyride 1.10.2"	https:// github.com/ geosolutions-it/ react-joyride/ tree/release
mocha	6.2.0- uncaught	#3693	Customized in order to make some test run. More in detail, we removed uncaught exceptions handler because it was making some test failing (waiting for a better solution). Published "@geosolutions/mocha 6.2.1-3". mocha is being moved from node_modules/@geosolutions/ mocha to node_modules/mocha in order to make the test be runnable	https:// github.com/ geosolutions-it/ mocha/tree/ release_v6.2.1
jsdoc	3.4.3	#1978	ES6 syntax not parsed by Docma, so we published "@geosolutions/ jsdoc 3.4.4" with other related dependencies also on our npm, like acorn-jsx, espree and tv4	https:// github.com/ geosolutions-it/ jsdoc/tree/ release
acorn-	4.0.1	#1978	Added support for instance	https://

## Aliases

Only proj4 and react-joyride are using aliases in order to maintain original webpack requires like:

- const proj4 = require("proj4");
- const joyride = require('react-joyride').default;

see this for current status of aliases

# More info

Here you can find more information about customization

# Styling and Theming

The look and feel is completely customizable either using one of the included themes, or building your own. Themes are built using less. You can find the default theme here: https://github.com/geosolutions-it/ MapStore2/tree/master/web/client/themes/default

## Theme Structure

```
+-- themes/
 +-- theme-name/
       +-- icons/
           +-- icons.eot
           +-- icons.svg
           +-- icons.ttf
            +-- icons.woff
           +-- icons.woff2
       +-- img/
       +-- less/
           +-- mixins/
               +-- bootstrap.less
               +-- css-properties.less
               +-- theme.less
           +-- mapstore.less
            +-- common.less
            +-- style-module.less
            +-- .less files for all the other modules
       +-- base.less
       +-- bootstrap-theme.less
       +-- bootstrap-variables.less
       +-- icons.less
       +-- ms2-theme.less
       +-- ms-variables.less
       +-- theme.less
       +-- variables.less
```

theme.less is the entry point for all the main imports and it needs to be properly required in buildConfig.js or in your webpack.config.js in the themeEntries.

theme.less	imports
------------	---------

file	description
base.less	contains a declaration of font colors and background defined for data- ms2-container attribute which is usually the body tag
icons.less	contains font-face declaration for glyphs, it extends the bootstrap glyphicons to use custom MapStore icons
bootstrap- theme.less	contains all the less style for bootstrap components
ms2-theme.less	contains all the less style for MapStore components
variable.less	contains the import of mapstore variables and the override of bootstrap variables

below an example of entry configuration:

```
entry: {
    ...other entries,
    'themes/theme-name': path.join(__dirname, 'path-to', 'theme-
name', 'theme.less')
},
```

MapStore uses a themeEntries function to automatically create the entries for default themes that can be found under the web/client/themes directory

```
const themeEntries = require('./themes.js').themeEntries;
entry: {
    ...other entries,
    ...themeEntries
},
```

Default themes in web/client/themes directory are useful to have an overview of the structure described above.

Note: we suggest to place the theme folder inside a themes directory for MapStore project

#### Structure of .less files

Each less file that represent a MapStore plugin or component is composed by two sections:

- Theme section includes all the styles and classes that should change based on css variables. All the new declared selector must be included in a special function called #ms-components-theme. The #ms-components-theme function provide access to all the available variables of the theme via the @theme-vars argument.
- Layout section includes all the styles and classes that should not change in a simple customization.

#### Example:

#### ms-variables.less

MapStore uses basic less variables to change theme colors, buttons sizes and fonts. It possible also to override bootstrap less variable for advanced customization. Basic variables can be found in the ms-variable.less file

New declarations in MapStore should have the following structure:

```
global: @ms-rule-value
```

```
local: @ms-name-of-plugin--rule-value
```

- @ms suffix for MapStore variable
- name-of-plugin for local variable it's important to write the name of plugin in kebab-case
- rule-value value to use in compiled CSS, some examples:
- color generic color variable
- text-color color for text
- background-color color for background
- border-color color for border

#### less/ directory

The less/ directory contains all the modules needed to create the final CSS of MapStore.

Each file in this directory is related to a specific plugin or component and the files are named based on the plugin's name are referring to.

common.less file can be used for generic styles.

#### inline styles

Inline styles should be applied only for values that change dynamically during the lifecycle of the application, all others style should be moved to the related .less file.

The main reason of this choice is to allow easier overrides of styles in custom projects.

### Add New Theme

To support a new theme for mapstore product:

- 1. create a new folder in the themes folder with the name of your theme
- 2. create less files in the folder (at least theme.less, as the main file and variables.less, to customize standard variables)
- 3. add the new theme to the index file, with the id corresponding to the theme folder name

If you are not using themeEntries a new entry needs to be added in the buildConfig.js

You can then switch your application to use the theme adding a new section in the appConfig.js file:

```
initialState: {
    defaultState: {
```

```
...
theme: {
    selectedTheme: {
        id: <your theme id>
        }
    },
    ...
}
```

### Custom Theme for project

In a mapstore project normally the theme configuration is placed in the themes/ directory

Styles can be overridden declaring the same rules in a less module placed in a new project.

Below steps to configure a custom theme and override styles:

• add the following files to the themes folder of the project:

```
.
+-- themes/
| +-- default/
| +-- less/
| +-- my-custom-module.less
| +-- theme.less
| +-- variables.less
```

• import in theme.less all the needed less module

```
@import "../../MapStore2/web/client/themes/default/theme.less";
@import "./variables.less";
@import "./less/my-custom-module.less";
```

 update webpack configuration to use the custom style (webpack.config.js, prod-webpack.config.js)

```
module.exports = require('./MapStore2/buildConfig')(
        {
            '__PROJECTNAME__': path.join(__dirname, "js", "app"),
            '_PROJECTNAME__-embedded': path.join(__dirname,
            "MapStore2", "web", "client", "product", "embedded"),
            '_PROJECTNAME__-api': path.join(__dirname,
            "MapStore2", "web", "client", "product", "api")
        },
        themeEntries,
        + {
            ' themes/default": path.join(__dirname, "themes",
            "default", "theme.less")
        + },
        ...
```

• update variables.less to override existing variables

```
/* change primary color to blue */
@ms-primary: #0000ff;
```

• update my-custom-module.less to override existing rules or add new rules

```
/* change the background color of the page*/
.page {
    background-color: #d9e6ff;
}
```

### Custom Theme for contexts

You can configure a list of themes to be used inside a context.

In order to do that you have to:

- create the themes in the themes/ folder as described below
- edit ContextCreator plugin in the localConfig.json

example

```
{
    "name": "ContextCreator",
    "cfq": {
        "documentationBaseURL": "https://
mapstore.geosolutionsgroup.com/mapstore/docs/api/plugins",
        "backToPageDestRoute": "/context-manager",
        "backToPageConfirmationMessage": "contextCreator.undo",
        "themes": [{
                "id": "complete-theme-override",
                "type": "link",
                "href": "dist/themes/complete-theme-
override.css".
                "defaultVariables": {
                    "ms-main-color": "#000000",
                     "ms-main-bg": "#FFFFFF",
                    "ms-primary-contrast": "#FFFFFF",
                    "ms-primary": "#078aa3",
                    "ms-success-contrast": "#FFFFFF",
                    "ms-success": "#398439"
                }
            },
            {
                "id": "partial-theme-override",
                "type": "link",
                "href": "dist/themes/partial-theme-override.css"
            },
            {
                "id": "only-css-variables",
                "type": "link",
                "href": "dist/themes/only-css-variables.css"
            }
        ],
        "basicVariables": {
            "ms-main-color": "#000000".
            "ms-main-bg": "#FFFFFF",
            "ms-primary-contrast": "#FFFFFF",
            "ms-primary": "#078aa3",
            "ms-success-contrast": "#FFFFFF",
            "ms-success": "#398439"
        }
   }
}
```

for each theme you can define:

· id id of the theme equal to its name

- type values can be
- · link will require a href property
- href path to find the css once built
- **defaultVariables** variables of the theme used to initialize the pickers (optional)

**basicVariables** these are the variables used as default values if a theme is not selected (optional)

# Suggested ways to create a custom theme for a context

### Complete theme override

This example will create a complete css file and is not recommended if you want a light version and you just need to customize the variables (for this check next paragraph)

Add the following files to the themes folder of the project

```
+-- themes/
| +-- theme-name/
| +-- theme.less
| +-- variables.less
```

in theme.less put

```
/*
 * This example will contain a complete mapstore theme with
some customization
 * it will be selectable inside context theme step selector
*/
/*
 * it includes the main theme and this will recompile the whole
theme
*/
```

```
@import "../../MapStore2/web/client/themes/default/theme.less";
/*
 * it includes some changes to css variables
*/
@import "./variables.less";
/*
 * Note: You can always expand it with new less/css rules
*/
```

in variables.less you can put the mapstore variables customizations

```
/*
 * A variable that will override the default css one
*/
@ms-primary: #2E13FE;
```

#### Only css variables

This example is perfect if you just want to customize a few colors of the theme

```
+-- themes/
| +-- theme-name/
| +-- theme.less
| +-- variables.less
```

in theme.less put

```
/*
 * This example is the lightest version of all three examples
 * it will be selectable inside context theme step selector
 * this examples is limited to changing the css variables only,
 * but you can always expand it as we did for partial-theme-
override
 */
/*
 * This will import as (reference) https://lesscss.org/features/
#import-atrules-feature-reference
 * It's used to import external files, but without adding the
```

```
imported styles
* to the compiled output unless referenced.
*
*/
@import (reference) "../../MapStore2/web/client/themes/default/
theme.less";
/*
* it includes some changes to css variables
*/
@import "./variables.less";
/*
* this will create only one class with the :root selector
inside
* it's important to place the variable overrides before
calling the css-variable mixin generator
* which is called .get-root-css-variables
*/
.get-root-css-variables(@ms-theme-vars);
/*
* Note: You can always expand it with new less/css rules
*/
```

In the variables.less you can do put your variable customizations

#### partial theme override

```
+-- themes/
| +-- theme-name/
| +-- less/
| +-- plugin-name.less
```

```
/*
 * We can use this method when we want to customize some part
of the theme
 * without the need to include the theme in its completeness
*/
/*
 * here you can apply some other overrides, like the size of
thumbnails for backgrounds
```

```
*/
@import "./less/drawer-menu.less";
/*
* Note: You can always expand it with new less/css rules
*/
```

Note: These three styles are an example on how is possible to approach on the mapstore customizations. You could extend/combine them together to create a more complex theme.

### Tips

- When you develop locally
- and you want to reduce the building time
- and you don't need themes that are not the default theme
- then you can comment this in the webpack-config.js

# Working with Extensions

The MapStore2 plugins architecture allows building your own independent modules that will integrate seamlessly into your project.

Extensions are plugins that can be distributed as a separate package (a zip file), and be installed, activated and used at runtime. Creating an extension is similar to creating a plugin. If you are not familiar with plugins, please, read the Plugins HowTo page first.

### Developing an extension

The easiest way to develop an extension is to start from the MapStoreExtension project that gives you a sandbox to create/test and build your extension.

Read the readme of the project to understand how to run, debug and build a new extension starting from the sampleExtension in the project.

Here you can find some details about the structure extension files, useful for development and debugging.

### An extension example

A MapStore extension is a plugin, with some additional features.

```
import {connect} from "react-redux";
import Extension from "../components/Extension";
import Rx from "rxjs";
import { changeZoomLevel } from "../../../web/client/actions/
map";
export default {
    name: "SampleExtension",
    component: connect(state => ({
        value: state.sampleExtension &&
    state.sampleExtension &&
```

```
}), {
        onIncrease: () => {
            return {
                type: 'INCREASE_COUNTER'
            };
        }, changeZoomLevel
    })(Extension),
    reducers: {
        sampleExtension: (state = { value: 1 }, action) => {
            if (action.type === 'INCREASE_COUNTER') {
                return { value: state.value + 1 };
            }
            return state;
        }
    },
    epics: {
        logCounterValue: (action$, store) =>
action$.ofType('INCREASE_COUNTER').switchMap(() => {
            /* eslint-disable */
            console.log('CURRENT VALUE: ' +
store.getState().sampleExtension.value);
            /* eslint-enable */
            return Rx.Observable.empty();
        })
    },
    containers: {
        Toolbar: {
            name: "SampleExtension",
            position: 10,
            text: "INC",
            doNotHide: true,
            action: () => {
                return {
                    type: 'INCREASE_COUNTER'
                };
            },
            priority: 1
       }
   }
};
```

As you can see from the code, the most important difference is that you need to export the plugin descriptor **WITHOUT** invoking createPlugin on it (this is done in extensions.js in dev environment and when installed it will be done by the extensions load system). The extension definition will import or define all the needed dependencies (components, reducers, epics) as well as the plugin configuration elements (e.g. containers).

### Dynamic import of extension

MapStore supports dynamic import of plugins and extensions.

Dynamically imported plugins or extensions uses lazy-loading: components, reducers and epics will be loaded once plugin or extension is in the list of plugins configured for the current page (eg. via localConfig.json or plugins selected to be included in a context).

Note

Application context could have plugins configured to be loaded optionally using the Extensions Library. Such plugins will be loaded only after being directly activated by the user in the extensions library UI.

Regardless if extension uses lazy-loading or not, its epics will be muted once extension is not rendered on the page. For more details see Epic state.

There are few changes required to make extension loaded dynamically:

- 1. Create Module.jsx file in js/extension/plugins/ and populate it with js/ extension/plugins/Extension.jsx content.
- 2. Update content of js/extension/plugins/Extension.jsx to be like:

```
import {toModulePlugin} from "@mapstore/utils/
ModulePluginsUtils";
import { name } from '../../config';
export default toModulePlugin(name, () => import(/*
webpackChunkName: 'extensionName' */ './Module'));
```

3. Update js/extensions.js and remove createPlugin wrapper from Extension export. File content should look like:

```
import Extension from './extension/plugins/Extension';
import { name } from '../config';
export default {
    [name]: Extension
};
```

Distributing your extension as an uploadable module

The sample project allow you to create the final zip file for you.

The final zip file must have this form:

- the file named index.js is the main entry point, for the module.
- an index.json file that describes the extension, an example follows
- assets folder, that contains additional bundles (js, css) came out from the bundle compilation. All additional files (js chunks, css ...) must stay in this folder.
- optionally, a translations folder with localized message files used by the extension (in one or more languages of your choice)

#### index.json

The `index.json file should contain all the information about the extension:

- An id that identifies the extension
- A version to show in UI. Semantic versioning is suggested.+
- title and description to display in UI, mnemonic hints for the administrator
- plugins the list of plugins that it adds to the application, with all the data useful for the context manager. Format of the JSON object for plugins is suggested here

```
{
    "id": "a_unique_extension_identifier",
    "version": "1.0.0",
    "title": "the title of the description",
    "description": "a description of the extension",
    "plugins": [{
        "name": "MYPlugin",
        "title":
    "extensions.a_unique_extension_identifier.title",
        "defaultConfig": {},
        "...": "..."
    }]
}
```

plugins section contains the plugins defined in the extension, and it is needed to be configured in the context-editor. See Context Editor Configuration

### Installing Extensions

Extensions can be uploaded using the context creator UI of MapStore. The storage and configuration of the uploaded zip bundle is managed by a dedicated MapStore backend service, the **Upload Service**. The Upload Service is responsible for unzipping the bundle, storing javascript and the other extension

assets in the extensions folder and updating the configuration files needed by MapStore to use the extension:

- extensions.json (the extensions registry)
- pluginsConfig.json.patch (the context creator plugins catalog patch file)

#### **Updating Extensions**

Please refer to the How to update extensions section of user guide to get more information about extensions update workflow.

#### Extensions and datadir

Extensions work better if you use a datadir, because when a datadir is configured, extensions are uploaded inside it, so they can *live* outside the application main folder (and you don't risk to overwrite them when you upgrade MapStore to a newer version).

### Extensions for dependent projects

Extensions build in MapStore actually can run only in MapStore product. They can not be installed in dependent projects. If you have a custom project, and you want to add support for extensions, you will have to create your build system for extensions dedicated to your application, to build the Javascript with the correct paths. Moreover, to enable extensions to work with the datadir in a dependent project (MapStore product is already configured to use it) you need to configure (or customize) the following configuration properties in your application:

#### Externalize the extensions configuration

Change app.jsx to include the following statement:

ConfigUtils.setConfigProp("extensionsRegistry", "rest/config/ load/extensions.json");

#### Externalize the context plugins configuration

Change app.jsx to include the following statement:

```
ConfigUtils.setConfigProp("contextPluginsConfiguration", "rest/
config/load/pluginsConfig.json");
```

#### Externalize the extensions assets folder

Change app.jsx to include the following statement:

```
ConfigUtils.setConfigProp("extensionsFolder", "rest/config/
loadasset");
```

Assets are loaded using a different service, /rest/config/loadasset.

### Managing drawing interactions conflict in extension

Extension could implement drawing interactions, and it's necessary to prevent a situation when multiple tools from different plugins or extensions have active drawing, otherwise it could end up in an unpredicted or buggy behavior.

There are two ways how drawing interaction can be implemented in plugin or extension:

- Using DrawSupport (e.g. Annotations plugin)
- By intercepting click on the map interactions (e.g. Measure plugin)

#### Making another plugins aware of your extension starts drawing

If your extension using DrawSupport - you're on the safe side. Extension will dispatch CHANGE\_DRAWING\_STATUS action. This action can be traced by another plugins or extensions, and they can control their tools accordingly.

If your extension is using CLICK\_ON\_MAP action and intercepts it perform any manipulations on click - you need to make sure that your extension also dispatch

REGISTER\_EVENT\_LISTENER action (see Measure plugin as an example) when your extension activates drawing.

It should also dispatch UNREGISTER\_EVENT\_LISTENER once drawing interaction stops.

#### Making your extension aware of another plugin drawing

There is a helper utility named shutdownToolOnAnotherToolDrawing. This is a wrapper for a common approach to dispatch actions that will toggle off drawing interactions of your extension whenever another plugin or extension starts drawing.

extensionEpics.js:

```
export const toggleToolOffOnDrawToolActive = (action$, store)
=> shutdownToolOnAnotherToolDrawing(action$, store,
'yourToolName');
```

with this code located in extension's epics your tool yourToolName will be closed whenever:

- feature editor is open
- another plugin or extension starts drawing.

"shutdownToolOnAnotherToolDrawing" supports passing custom callback to determine whether your tool is active (to prevent garbage action dispatching if it's already off) and custom callback to list actions to be dispatched.

### Using "ResponsiveContainer" for dock panels

Starting with MapStore v2022.02.00, layout improvements have been introduced which, in addition to other changes, introduce a new sidebar menu to be used instead of the burger menu.

All extensions using DockPanel or DockablePanel components have to be updated if their dock panel is rendered on the right side of the screen, next to the new sidebar menu.

Following changes should be applied (MapTemplates plugin can be a reference for the changes needs to be applied):

1. Make your extension aware of the map layout changes by getting corresponding state value using following selector:

```
createSelector(
    ...
    state => mapLayoutValuesSelector(state, { height: true,
right: true }, true),
    ...
    (dockStyle) => ({
        dockStyle
    })
)
```

It will get offset from the right and the bottom that needs to be applied to the ResponsiveContainer

2. Replace DockPanel, DockablePanel, ContainerDimensions (if used) with the ResponsiveContainer and make sure that dock content is a child of ResponsiveContainer:

was:

```
return (
        <DockPanel
            open={props.active}
            position="right"
            size={props.size}
            bsStyle="primary"
            title={<Message msgId="mapTemplates.title"/>}
            style={{ height: 'calc(100% - 30px)' }}
            onClose={props.onToggleControl}>
            {!props.templatesLoaded && <div className="map-
templates-loader"><Loader size={352}/></div>}
        {props.templatesLoaded && <MapTemplatesPanel
            templates={props.templates}
            onMergeTemplates}
        </pre>
```

```
onReplaceTemplate={props.onReplaceTemplate}
onToggleFavourite={props.onToggleFavourite}/>}
</DockPanel>
)
```

become:

```
return (
    <ResponsivePanel
        containerStyle={props.dockStyle}
        style={props.dockStyle}
        containerId="map-templates-container"
        containerClassName="dock-container"
        className="map-templates-dock-panel"
        open={props.active}
        position="right"
        size={props.size}
        bsStyle="primary"
        title={<Message msgId="mapTemplates.title"/>}
        onClose={props.onToggleControl}
    >
        {!props.templatesLoaded && <div className="map-</pre>
templates-loader"><Loader size={352}/></div>}
        {props.templatesLoaded && <MapTemplatesPanel</pre>
            templates={props.templates}
            onMergeTemplate={props.onMergeTemplate}
            onReplaceTemplate={props.onReplaceTemplate}
            onToggleFavourite={props.onToggleFavourite}/>}
    </ResponsivePanel>
);
```

With the applied changes dock will be rendered properly both for layout with BurgerMenu and SidebarMenu.

# Making other dock panels closed automatically when extension panel is open

All the dock panels open next to the sidebar should be mutually excluded. Active dock panel should be closed whenever another panel is open.

Array at state.maplayout.dockPanels.right contains list of panels that can be extended or modified by extension by dispatching updateDockPanelsList action.

Please note that adding dock into the list will automatically close previously active panel, so it's a good idea to dispatch the action on app initializing or when dock panel is open. Measurement plugin can be used as a reference of implementation, see openMeasureEpic & closeMeasureEpic in epics/ measurement.js.

# Printing Module

The **printing module** of MapStore is a back-end service **not included by default in the binary package** that allows to create a printable PDF from the current map.

The **printing module** is required by the **Print plugin** of MapStore, so if you want to have the Print plugin working in your application, you have to include also the printing module in your MapStore installation.

# Including the printing module in MapStore

Because MapStore doesn't include the printing module by default, to use it you need to build from the source a MapStore.war that includes it or add the missing files to an existing MapStore deployed.

### Building from the Source

If you want to include the printing module in your MapStore, by building the source code, you have to add the profile printing (profiles can be added as 2nd argument of the build.sh script, after the version that is the 1st. If you have more then one profile, you can add them separated by , ):

./build.sh [version\_identifier] printing

MapStore projects also allow to use the printing profile to include this module. So you can use the same printing profile to build your custom MapStore project including the printing module.

### Adding to an existing MapStore

If you have an existing and deployed instance of MapStore and you want to add the printing module, you can build only the printing extension as a zip running mvn clean install -Pprintingbundle from the official Mapstore project. The zip bundle will created in java/printing/target/mapstore-printing.zip.

You can copy the content of this zip bundle into the root of mapstore application (<app\_root>, for instance webapps/mapstore in Tomcat):

- files from zip directory WEB-INF/classes must be placed in <app\_root>/ WEB-INF/classes
- files from zip directory WEB-INF/lib must be placed in <app\_root>/WEB-INF/lib

for the printing configuration files (if they are missing)

• these files must be placed in <app\_root>/printing

Then restart your java container.

### Configuring the print

This printing module includes the MapStore printing engine, that is a fork of MapPhish print (version 2), with some additional functionalities you can find in the Wiki page.

Inote: The module was originally written for GeoServer, so on the Github wiki you can find information about downloading and installing it in GeoServer, but if you include the engine directly in MapStore you don't need any other installation.

#### MapStore

The MapStore print module on the front-end is implemented by the Print plugin inside localConfig.json. Make you sure to have this plugin in plugins/(mode) section. If so, this will will automatically check the presence of the back-end module and show the entry in the Burger Menu, if the back-end service is present.

In localConfig.json you will find also a printUrl configuration that refers to the (relative) URL where the main entry point of the application is available. (the default should enough)

### **Print Settings**

This fork uses the same configuration files of the original library to define the various print layouts and options. This files is in the directory resources/ geoserver/print, and they will be copied in WEB-INF/classes in the final war file.

- config.yml : The main file that configures the layout. More information about this configuration file in the original documentaiton
- print\_header.png: The header, referred in config.yml
- Arrow\_north\_CFCF.svg the north indicator, referred in config.yml

# Troubleshooting

#### I can not see the "Print" entry in the menu

Please check if:

- "Print" plugin is present in localConfig.json --> plugins --> desktop.
- You are using a desktop browser. The plugin is not designed for a mobile devices (tablet, smartphone...), for this reason it is not included in plugins
   --> mobile

- The service at url http(s)://<your-domain>/<applciation-base-paath>/ pdf/info.json is responding. Example: https://example.com/mapstore/ pdf/info.json. The URL of this info.json is configured (by default as relative URL) in localConfig.json --> printUrl entry.
- Looking at the JSON returned by the request above, the URLs in the entries printURL and createURL are reachable, and the domain, (the port) and the schema (http/https) of these URLs are the same of MapStore.

### I have an error printing (using Reverse Proxy/HTTPS)

When you open MapStore from the browser, MapStore do a request to the main entry point ( info.json ) of the printing module. This entry point provides a set of URLs where to find all the print related services. These URLs are generated starting from the current request.

A common practice is to use a reverse proxy in front of a Java Application Server, and so MapStore (this is used also to add https, if the reverse proxy is part of a web server). If this reverse proxy is not properly configured anyway, MapStore will not be able to correctly generate the URLs of the printing services, and this may cause an error when you try to print a PDF.

To avoid this problem, you can use several solution, depending on your setup and your reverse proxy.

#### Setting up your proxy

Some typical solutions are:

• Using AJP instead of http (this forwards all the information by default)

```
# Example for Apache HTTP server
ProxyPass /mapstore ajp://localhost:8010/mapstore
ProxyPassReverse /mapstore ajp://localhost:8010/mapstore
```

• Using rewrite engine to rewrite the requests. (apache web server)

```
# example for Apache HTTP server
RewriteEngine On
RewriteCond %{HTTPS} off
RewriteRule ^ https://%{HTTP_HOST}%{REQUEST_URI}
RedirectMatch ^/$ /mapstore/
ProxyRequests Off
ProxyPreserveHost On
ProxyVia full
```

• Using non-standard headers, X-Forwarded-Host and X-Forwarded-Proto.

```
# example for nginx
proxy_set_header X-Forwarded-Proto https;
```

#### Forcing PRINT\_BASE\_URL of printing module

If, for any reason, you can not modify the proxy configuration, MapStore printing module provides a system variable PRINT\_BASE\_URL that you can set to force the URLs returned by info.json to be resolved from it.

A useful trick can be to set as a relative URL (relative to MapStore) to make it work in any context (only for MapStore).

```
JAVA_OPTS= "$JAVA_OPTS -DPRINT_BASE_URL=pdf"
```

or you can use the absolute URL:

```
JAVA_OPTS= "$JAVA_OPTS -DPRINT_BASE_URL=https://example.com/
mapstore/pdf"
```

# How to use a CDN

The LeafletDraw plugin and the MapStore theme are linked via rawgit.com but in production it should be used a proper CDN. Once you have a stable version:

- upload the LeafletDraw plugin and the MapStore theme on your CDN
- edit the index.html file to use your published resources.

# FAQ

# Troubleshooting

#### Autowatch doesn't work on Linux

You should need to increase max\_user\_watches variable for inotify.

```
echo fs.inotify.max_user_watches=524288 | sudo tee -a /etc/
sysctl.conf && sudo sysctl -p
```

## Other References

How to use a CDN

# Code conventions

In order to preserve quality, maintainability and testability when you develop in MapStore you should follow the following rules and best practices.

### TL;DR

- · Access to the state using state selectors
- Prefer plugins cfg over initialState for plugins configurations
- Use web/client/libs/ajax in your hooks or in redux-observable for async

### Access to the state using state selectors

Is **strongly recommended** to not access to the state directly inside the mapStateToProps function of react-redux . Use (or define) selectors in the selectors directory. This provides the following advantages:

- Selectors can be reused in epics.
- · Ready to use optimization with reselect
- Simplify future refactoring
- Easy unit testing and bug identification

Wrapping all the access to the state inside well-defined selector makes easier to add functionalities and will increase code maintainability. You should always reuse existing selectors (or create new ones) to access to the application state for core application functionalities. It will help also future refactoring because any change to the state structure (from the reducer point of view) or data source (from the components point of view) requires only changes to the interested selectors.

A selector should be placed into the proper selectors/<state-slice>.js file with the same name of the relative reducer. When a selector retrieves data from

more than one state slices, you should place it in the selector nearest by concern. For instance isFeatureGridOpen should be placed into featuregrid

If you don't work on a core functionality, where the state is shared between many components, defining the selector directly in the plug-in is not denied.

### Prefer plugin configuration over initialState

In order to create self contained plugins that can be reused you should prefer to configure the plugins using cfg. Using initialState should be considered deprecated. When the configuration is needed at an higher level (e.g. application state, for epics or to share this information), you should properly initialize the state of the plugin on your own triggering an action on mount/unmont. (cfg are passed to the plugin as react props).

### Use custom axios version for async requests

Using web/client/libs/ajax (a customized axios with some interceptors) for AJAX request contains interceptors to support proxyUrl and authenticationRules settings specified in localConfig.json, so you should prefer to use this enhanced version of axios.

Using axios + RxJS means that you will have to wrap axios calls in something like:

```
Rx.Observable.defer( () => axios.post(...)).map...
```

Use defer to allow the usage of RxJS retry. We still not support real AJAX cancellation at all, but we would like to provide some utility function/operator to bind axios cancellation functionalities into the RxJS flow in the future.

# Documentation guidelines

Each new feature/tool in MapStore should be documented in the User Guide in order to explain the involved functionalities and illustrate how it works.

All new front-end technologies, development procedures, best practices and guidelines on the involved components in MapStore should be properly documented too: the Developers Guide must be kept up-to-date for this.

The Developer and User guide documentation are built on the Read the Docs hosting platform. The MapStore's documentation files are available in the docs/ section of this repository; Mkdocs is used in MapStore as documentation generator, you can look at the available online documentation for more information on how to use it (MapStore uses his own customized MkDocs Material theme for both User and Developer documentations).

### General Guidelines

### Internal links

When creating internal links between pages ( .md files), make sure to use **full link** to the paragraph instead of using only the relative path to the file. As using relative path will not work in exported PDF document.

Example

```
Instead of creating a link [FAQ]('../dev-faq/'), use [FAQ]('../dev-faq/#faq') or [FAQ]
('../dev-faq.md#faq') or [FAQ]('dev-faq.md#faq')
```

# Building documentation

The documentation is built on RTD (Read the Docs) documentation hosting platform.

But in order to build it locally, there are certain steps that needs to be followed:

#### 1. Python installation

Install **Python 3** and **pip** following the instructions on the python web site for your operating system.

### 2. Libraries installation

Install **all** the libraries/plugins in docs/requirements.txt using **pip** while matching the exact version present.

pip install -r docs/requirements.txt

#### 3. Build the documentation

Build the docs using the command mkdocs build.

If you want to generate also the **PDF**, you need to add set the environment variable ENABLE\_PDF\_EXPORT to 1 before to run mkdocs build. The build with the PDF option takes around 5 minutes to finish.

```
export ENABLE_PDF_EXPORT=1
mkdocs build
```

This will build the documentation and puts the built files into site folder and the pdf generated into site\pdf\mapstore\_documentation.pdf

The documentation can be launched using index.html in site folder

### 4. Editing the documentation

To live build and test the documentation locally, run the following command:

mkdocs serve

This command will start the built-in dev-server of MkDocs that lets us preview the documentation as we work on it.

The documentation will be available at http://localhost:8000. Every time you save some documentation file, the page will be automatically updated.

# Migration Guidelines

# General update checklist

- updating an existing installation
- updating a MapStore project created for a previous version

To update an existing installation you usually have to do nothing except eventually to execute queries on your database to update the changes to the database schema.

In case of a project it becomes a little more complicated, depending on the customization.

This is a list of things to check if you want to update from a previous version valid for every version.

- Take a list to migration notes below for your version
- Take a look to the release notes
- update your package.json to latest libs versions
- take a look at your custom files to see if there are some changes (e.g. localConfig.js, proxy.properties)
- Some changes that may need to be ported could be present also in pom.xml files and in configs directory.
- check for changes also in web/src/main/webapp/WEB-INF/web.xml.
- Optionally check also accessory files like .eslinrc , if you want to keep aligned with lint standards.
- Follow the instructions below, in order, from your version to the one you want to update to.

# Migration from 2022.02.02 to 2023.01.00

### Log4j update to Log4j2

With this release Log4j has been updated to Log4j2. The Log4j API has changed with version 2. Basically if you customized logging properties, you have to update the properties file following the log4j properties file migration section.

If you have a downstream project, you will have also to update your dependencies in pom.xml and your Java code, following the suggestions in log4j2 dependencies and code update section.

For more information or more details about how to migrate, follow the official documentation.

Inote: A compatibility tier has been added in order to allow to use old configurations. Anyway it is strongly suggested to update your files as soon as possible.

#### log4j2 properties file migration

To have logging properly work on MapStore then it is needed to:

- Rename log4j.properties file to log4j2.properties.
- Edit the properties to configure it according to the log4j2 syntax. See the Configuration with Properties section on the official documentation page. Below the old and the new default log4j configuration files are juxtaposed:

log4j.properties

```
log4j.rootLogger=INFO, fileAppender
log4j.appender.consoleAppender=org.apache.log4j.ConsoleAppender
log4j.appender.consoleAppender.layout=org.apache.log4j.PatternLayo
log4j.appender.consoleAppender.layout.ConversionPattern=%p
%d{yyyy-MM-dd HH:mm:ss.SSS} %c::%M:%L - %m%n
```

log4j.logger.it.geosolutions.geostore.services.rest=INFO

```
log4j.logger.org.hibernate=INF0
log4j.logger.com.trg=INF0
# File appender
log4j.appender.fileAppender=org.apache.log4j.RollingFileAppender
log4j.appender.fileAppender.layout=org.apache.log4j.PatternLayout
log4j.appender.fileAppender.layout.ConversionPattern=%p
%d{yyyy-MM-dd HH:mm:ss.SSS} %C{1}.%M() - %m %n
log4j.appender.fileAppender.File=${catalina.base}/logs/
mapstore.log
```

log42.properties

```
rootLogger.level = INF0
appenders= console, file
```

```
appender.console.type = Console
appender.console.name = LogToConsole
appender.console.layout.type = PatternLayout
appender.console.layout.pattern = %p %d{yyyy-MM-dd
HH:mm:ss.SSS} %c::%M:%L - %m%n
rootLogger.appenderRef.stdout.ref = LogToConsole
rootLogger.appenderRef.console.ref = LogToConsole
```

```
appender.file.type = File
appender.file.name = LogToFile
appender.file.fileName=${sys:catalina.base}/logs/mapstore.log
appender.file.layout.type=PatternLayout
appender.file.layout.pattern=%p %d{yyyy-MM-dd HH:mm:ss.SSS}
%C{1}.%M() - %m %n
rootLogger.appenderRef.file.ref = LogToFile
```

```
logger.restsrv.name=it.geosolutions.geostore.services.rest
logger.restsrv.level= INF0
logger.hibernate1.name=org.hibernate
logger.hibernate1.level=INF0
logger.trg1.name=com.trg
logger.trg1.level=INF0
```

The main difference applies to how define the Log level on a per package basis. If in previous version of log4j a single property was defining both the package and the level now we need two distinct properties, one to define the name (the package) and the other for the level:

before

log4j.logger.it.geosolutions.geostore.services.rest=INF0

• now

```
logger.restsrv.name=it.geosolutions.geostore.services.rest
logger.restsrv.level= INF0
```

Note that the second part of the property key in the log4j2 (restsrv in the example) can be whatever string of choice, with the only requirement to be the same for the name and the level property.

#### log4j2 dependencies and code update

In your downstream project you will have to replace, where you used (typically in backend and web folders) the following dependencies:

```
<dependency>
    <groupId>log4j</groupId>
    <artifactId>log4j</artifactId>
    <version>${log4j.version}</version>
</dependency>
<dependency>
    <groupId>org.slf4j</groupId>
    <artifactId>slf4j-log4j12</artifactId>
    <version>${slf4j.version}</version>
</dependency>
<dependency>
   <groupId>org.slf4j</groupId>
    <artifactId>jcl-over-slf4j</artifactId>
    <version>${slf4j.version}</version>
</dependency>
 <dependency>
    <groupId>org.slf4j</groupId>
```

#### with

```
<dependency>
<groupId>org.apache.logging.log4j</groupId>
<artifactId>log4j-core</artifactId>
<version>2.19.0</version>
</dependency>
<dependency>
<groupId>org.apache.logging.log4j</groupId>
<artifactId>log4j-api</artifactId>
<version>2.19.0</version>
</dependency>
<dependency>
<groupId>org.apache.logging.log4j</groupId>
<artifactId>log4j-slf4j-impl</artifactId>
<version>1.7.2</version>
</dependency>
```

In the image of the image of

Moreover, if you have some custom code, you will hae to replace the use of getLogger . Example:

```
private static final Logger LOGGER =
Logger.getLogger(MyClass.class);
```

with

```
private static final Logger LOGGER =
LogManager.getLogger(MyClass.class);
```

where LogManager can be imported as:

## Update database schema

This new version introduced the attributes for user groups. This requires an update to your database applying the scripts available here. You have to apply the script \*-migration-from-v.1.5.0-to-v2.0.0 of your database. For instance on postgreSQL, you will have to execute the script postgresql/postgresql-migration-from-v.1.5.0-to-v2.0.0.

In ote: The script assumes you set the search path for your db schema. Usually in postgres it is geostore. So make you sure to set the proper search path before to execute the script in postgres. (e.g. SET search\_path T0 geostore; )

In ote: If you don't want to or you can not execute the migration script, you can set in geostore-datasource-ovr.properities the following property to make MapStore update the database for you

```properties
geostoreEntityManagerFactory.jpaPropertyMap[hibernate.hbm2ddl.autc

# Migration from 2022.02.00 to 2022.02.01

#### Package.json scripts migration

With this release we are refactoring a bit the naming of the scripts maintaining retro compatibility avoiding builds on ci/cd systems to break. Anyway we suggest to align them as listed here

The main changes are:

- We have removed travis and montest scripts.
- Most of the scripts are now prefixed with app or fe or be to make them more clear.

• Now npm start is an alias of npm run app:start and starts both frontend and back-end.

Although it is optional we suggest to align your project to these changes. In order to align your repository you should:

- update your package.json to latest scripts, you can copy them from utility/projects/projectScripts.json in MapStore2 repository.
- update your build.sh to use the latest scripts, instead of the old ones. See project/standard/templates/build.sh in MapStore2 repository.
- update in your repository web/pom.xml of your project to receive the backend property from ENV variables.

# Migration from 2022.01.02 to 2022.02.00

## HTML pages optimization

We removed script and css link to leaflet CDN in favor of a dynamic import of the libraries in the main bundle, now leaflet is only loaded when the library is selected as map type of the viewer. You can update the project HTML files by removing these tags:

```
- <link rel="stylesheet" href="https://cdnjs.cloudflare.com/
ajax/libs/leaflet/1.3.1/leaflet.css" />
- <link rel="stylesheet" href="https://cdnjs.cloudflare.com/
ajax/libs/leaflet.draw/1.0.2/leaflet.draw.css" />
<link rel="stylesheet" href="https://cdnjs.cloudflare.com/ajax/
libs/font-awesome/4.7.0/css/font-awesome.min.css" />
<link rel="shortcut icon" type="image/png" href="https://
cdn.jslibs.mapstore2.geo-solutions.it/leaflet/favicon.ico" />
<!--script src="https://maps.google.com/maps/api/js?v=3"></
script-->
- <script src="https://cdnjs.cloudflare.com/ajax/libs/leaflet/
1.3.1/leaflet.js"></script>
- <script src="https://cdnjs.cloudflare.com/ajax/libs/leaflet/
leaflet.draw/1.0.2/leaflet.draw.js"></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script>
```

We also made asynchronous the script to detect valid browser. This should slightly improve the initial requests time. You can updated the script in your project as following:

```
<script async type="text/javascript" src="https://unpkg.com/</pre>
bowser@2.7.0/es5.js" onload="checkBrowser()"></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></script></scrip
<script type="text/javascript">
                    function checkBrowser() {
                                       var browserInfo =
bowser.getParser(window.navigator.userAgent);
  var isValidBrowser = browserInfo.satisfies({
  "edge": ">1",
  "chrome": ">1",
  "safari": ">1",
  "firefox": ">1"
   });
   if (!isValidBrowser) {
   window.location.href = "unsupportedBrowser.html"
  document.querySelector("container").style.display =
"none";
   }
                    }
</script>
```

Update plugins.js to make upstream plugins use dynamic import

We've updated plugins.js in MapStore to make most of the plugins use dynamic import. plugins.js of your project have to be updated separately.

Please use web\client\product\plugins.js file as a reference listing plugins
whose definition can be changed to support dynamic import.

To use dynamic import for plugin, please update its definition to look like:

```
{
    ...
    AnnotationsPlugin: toModulePlugin('Annotations', () =>
import(/* webpackChunkName: 'plugins/annotations' */ '../
plugins/Annotations')),
    ...
}
```

See Dynamic import of extension to have more details about transforming extensions to use dynamic import.

## Version plugin has been removed

We no longer maintain the Version plugin since we have moved its content inside the About plugin (see here for more details)

We suggest you to clean up your project as well:

- remove Version entry it from a local list of plugins.js
- remove Version entries it from a localConfig.json and pluginConfig.json
- add About entry into other pages of mapstore plugins array:
- dashboard
- geostory
- mobile
- remove DefinePlugin entries dedicated to git revision retrieved by gitrevision-webpack-plugin, if any, from webpack-config.js or prod.webpack-config.js, because they have been moved to the file build/BuildUtils.js
- · check that in your package.json you have this extends rule

```
"eslintConfig": {
    "extends": [
        "@mapstore/eslint-config-mapstore"
    ],
    ...
```

 edit the version of the @mapstore/eslint-config-mapstore to 1.0.5 in your package.json so that the new globals config will be inherited

## Support for OpenID

MapStore introduced support for OpenID for google and keycloak. In order to have this functionalities and to be aligned with the latest version of MapStore you have to update the following files in your projects:

 geostore-spring-security.xml (your custom spring security context) have to be updated adding the beans and the security:custom-filter entry in the <security:http> entry, as here below:

```
<security:csrf disabled="true"/>
        <security:custom-filter
ref="authenticationTokenProcessingFilter"
before="FORM_LOGIN_FILTER"/>
        <security:custom-filter
ref="sessionTokenProcessingFilter" after="FORM_LOGIN_FILTER"/>
        <security:custom-filter ref="keycloakFilter"</pre>
+
before="BASIC_AUTH_FILTER"/>
+
        <security:custom-filter ref="googleOpenIdFilter"</pre>
after="BASIC_AUTH_FILTER"/>
        <security:anonymous />
    </security:http>
    <security:authentication-manager>
        <security:authentication-provider
ref='geoStoreUserServiceAuthenticationProvider' />
    </security:authentication-manager>
÷
+
+ <bean id="preauthenticatedAuthenticationProvider"
class="it.geosolutions.geostore.services.rest.security.PreAuthenti
+ </bean>
+
+ <!-- OAuth2 beans -->
+ <context:annotation-config/>
+
    <bean id="googleSecurityConfiguration"</pre>
+
class="it.geosolutions.geostore.services.rest.security.oauth2.goog
>
+
+ <!-- Keycloak -->
+
+ <bean id="keycloakConfig"</pre>
class="it.geosolutions.geostore.services.rest.security.keycloak.Ke
```

```
+ <!-- END 0Auth2 beans-->
+
+ <!-- security integration inclusions -->
+ <import resource="classpath*:security-integration-$
{security.integration:default}.xml"/>
```

</beans>

• web.xml : add the following content to the file:

```
@@ -34,6 +34,17 @@
       <listener-
class>org.springframework.web.context.ContextLoaderListener
listener-class>
   </listener>

+
+
   <!-- Spring Security Servlet -->
   <filter>
```

 applicationContext.xml for consistency, we added mapstoreovr.properties files to be searched in class-path and in the data-dir, as for the other properties files:

## Upgrading the printing engine

The mapfish-print based printing engine has been upgraded to align to the latest official 2.1.5 in term of functionalities.

An update to the MapStore printing engine context file ( applicationContextprint.xml ) is needed for all projects built with the printing profile enabled. The following sections should be added to the file:

```
<bean id="configFactory"</pre>
class="org.mapfish.print.config.ConfigFactory"></bean>
+<bean id="threadResources"
class="org.mapfish.print.ThreadResources">
+ <property name="connectionTimeout" value="30000"/>
+ <property name="socketTimeout" value="30000" />
+ <property name="globalParallelFetches" value="200"/>
+ <property name="perHostParallelFetches" value="30" />
+</bean>
<bean id="pdfOutputFactory"</pre>
class="org.mapfish.print.output.PdfOutputFactory"/>
+
+<bean id="metricRegistry"
class="com.codahale.metrics.MetricRegistry" lazy-init="false"/>
+<bean id="healthCheckRegistry"
class="com.codahale.metrics.health.HealthCheckRegistry" lazy-
init="false"/>
+<bean id="loggingMetricsConfigurator"
class="org.mapfish.print.metrics.LoggingMetricsConfigurator"
lazy-init="false"/>
+<bean id="jvmMetricsConfigurator"
class="org.mapfish.print.metrics.JvmMetricsConfigurator" lazy-
init="false"/>
+<bean id="jmlMetricsReporter"
class="org.mapfish.print.metrics.JmxMetricsReporter" lazy-
init="false"/>
```

Also, remember to update your project pom.xml with the updated dependency:

- · locate the print-lib dependency in the pom.xml file
- · replace the dependency with the following snippet

```
<dependency>
    <groupId>org.mapfish.print</groupId>
    <artifactId>print-lib</artifactId>
    <version>geosolutions-2.1.0</version>
    <exclusions>
       <exclusion>
            <groupId>commons-codec</groupId>
            <artifactId>commons-codec</artifactId>
        </exclusion>
        <exclusion>
            <groupId>com.fasterxml.jackson.core</groupId>
            <artifactId>jackson-annotations</artifactId>
        </exclusion>
        <exclusion>
            <groupId>com.fasterxml.jackson.core</groupId>
            <artifactId>jackson-core</artifactId>
        </exclusion>
        <exclusion>
            <groupId>com.fasterxml.jackson.core</groupId>
            <artifactId>jackson-databind</artifactId>
        </exclusion>
        <exclusion>
            <groupId>org.springframework</groupId>
            <artifactId>spring-web</artifactId>
        </exclusion>
        <exclusion>
            <groupId>org.springframework</groupId>
            <artifactId>spring-context</artifactId>
        </exclusion>
    </exclusions>
</dependency>
```

Finally, to enable printing in different formats than PDF, you should add the following to your config.yml file (at the top level):

```
formats:
_ '*'
```

## Replacing BurgerMenu with SidebarMenu

There were several changes applied to the application layout, one of them is the Sidebar Menu that comes to replace Burger menu on map viewer and in contexts. Following actions need to be applied to make a switch:

• Update localConfig.json and add "SidebarMenu" entry to the "desktop" section:

```
{
    "desktop": [
        ...
        "SidebarMenu",
        ...
    ]
}
```

• Remove "BurgerMenu" entry from "desktop" section.

#### Using Sidebar Menu in new contexts

Contents of your pluginsConfig.json need to be reviewed to allow usage of new "SidebarMenu" in new contexts. Existing contexts need to be updated separately, please refer to the next chapter for instructions.

• Find "BurgerMenu" plugin configuration in pluginsConfig.json and remove "hidden": true line from it:

```
{
    "name": "BurgerMenu",
    "glyph": "menu-hamburger",
    "title": "plugins.BurgerMenu.title",
    "description": "plugins.BurgerMenu.description",
    "dependencies": [
        "OmniBar"
]
}
```

• Add SidebarMenu entry to the "plugins" array:

• Go through all plugins definitions and replace BurgerMenu dependency with SidebarMenu, e.g.:

```
{
    "name": "MapExport",
    "glyph": "download",
    "title": "plugins.MapExport.title",
    "description": "plugins.MapExport.description",
    "dependencies": [
        "SidebarMenu"
    ]
}
```

• Also the StreetView plugin needs to depend from SidebarMenu.

```
{
    "name": "StreetView",
    "glyph": "road",
    "title": "plugins.StreetView.title",
    "description": "plugins.StreetView.description",
    "dependencies": [
        "SidebarMenu"
    ]
}
```

#### Updating existing contexts to use Sidebar Menu

Contexts created in previous versions of MapStore will maintain old Burger Menu. There are two options allowing to replace it with the new Sidebar Menu:

- Using manual update.
- Using SQL query to update all contexts at once.

Before going with one of the approaches, please make sure that changes to pluginsConfig.json from previous chapter are applied.

#### To update context manually:

- 1. Go to the context manager (#/context-manager) and edit context you want to update.
- 2. Move to the step 3: Configure Plugins.
- 3. Find "Burger Menu" on the right side (enabled plugins) and move it to the left column.
- 4. Save context

**Note:** "Burger Menu" has higher priority over the "Sidebar Menu", so it will always be used if it's added to the list of enabled plugins of the context.

#### To update all contexts at once:

This is a sample SQL query that can be executed against the MapStore DB to replace the Burger Menu with the new Sidebar for existing application contexts previously created:

```
UPDATE geostore.gs_stored_data SET stored_data =
regexp_replace(gs_stored_data.stored_data,'{"name":"BurgerMenu"},'
FROM geostore.gs_resource
WHERE gs_stored_data.resource_id = gs_resource.id AND
        gs_resource.category_id = (SELECT id FROM
geostore.gs_category WHERE name = 'CONTEXT') AND
        gs_stored_data.stored_data ~
'.*{"name":"BurgerMenu"},.*';
```

Note: Schema name could vary depending on your installation configuration.

#### Updating extensions

Please refer to the extensions documentation to know how to update your extensions.

#### Using terrain layer type to define 3D map elevation profile

A new terrain layer type has been created in order to provide more options and versatility when defining an elevation profile for the 3D map terrain. This terrain layer will substitute the former wms layer (with useForElevation attribute) used to define the elevation profile.

Note

The wms layer (with useForElevation attribute) configuration is still needed to show the elevation data inside the MousePosition plugin and it will display the terrain at the same time. The terrain layer type allows a more versatile way of handling elevation but it will work only as terrain visualization in the 3D map viewer.

The additionalLayers object on the localConfig.json file should adhere now to the terrain layer configuration. Serve the following code as an example:

```
{
    "name": "Map",
    "cfg": {
        "additionalLayers": [{
            "type": "terrain",
            "provider": "wms",
            "url": "https://host-sample/geoserver/wms",
            "name": "workspace:layername", // name of the
geoserver resource
        "littleendian": false,
        "visibility": true
      }]
    }
}
```

Note

When using terrain layer with wms provider, the format option in layer configuration is not needed anymore as Mapstore supports only image/bil format and is used by default

# Migration from 2022.01.00 to 2022.01.01

## MailingLists plugin has been removed

MailingLists plugin has ben removed from the core of MapStore. This means you can remove it from your localConfig.json (if present, it will be anyway ignored by the plugin system).

# Migration from 2021.02.02 to 2022.01.00

This release includes several libraries upgrade on the backend side, in particular the following have been migrated to the latest available versions:

Library	Old	New
Spring	3.0.5	5.3.9
Spring-security	3.0.5	5.3.10
CXF	2.3.2	3.4.4
Hibernate	3.3.2	5.5.0
JPA	1.0	2.1
hibernate-generic-dao	0.5.1	1.3.0-SNAPSHOT
h2	1.3.168	1.3.175
javax-servlet-api	2.5	3.1.0

This requires also the upgrade of Tomcat to at least version 8.5.x.

#### Updating projects configuration

Projects need the following to update to this MapStore release:

• update dependencies (in web/pom.xml) copying those in MapStore2/java/ web/pom.xml, in particular (where present):

Dependency	Version	Notes
mapstore-services	1.3.0	Replaces mapstore-backend
geostore-webapp	1.8.0	

• update packagingExcludes in web/pom.xml to this list:

```
WEB-INF/lib/commons-codec-1.2.jar,
WEB-INF/lib/commons-io-1.1.jar,
WEB-INF/lib/commons-logging-1.0.4.jar,
WEB-INF/lib/commons-pool-1.3.jar,
WEB-INF/lib/slf4j-api-1.5*.jar,
WEB-INF/lib/slf4j-log4j12-1.5*.jar,
WEB-INF/lib/spring-tx-5.2.15*.jar
```

- upgrade Tomcat to 8.5 or greater
- update your geostore-spring-security.xml file to add the following setting, needed to disable CSRF validation, that MapStore services do not implement yet:

```
<security:http ... >
...
<security:csrf disabled="true"/>
...
</security:http>
```

remove the spring log4j listener from web.xml

- If one of the libraries updated is used in your project, you should align the version with the newer one to avoid jar duplications
- Some old project may define versions of spring and/or jackson in maven properties. You can remove these definition and the dependency from main pom.xml since they should be inherited from spring. In particular you may need to remove these properties :

#### Upgrading CesiumJS

CesiumJS has been upgraded to version 1.90 (from 1.17) and included directly in the mapstore bundle as async import.

Downstream project should update following configurations:

· remove all executions related to the cesium library from the pom.xml

```
<execution>
<id>html, configuration files and images</id>
<phase>process-classes</phase>
<goals>
<goal>copy-resources</goal>
</goals>
<configuration>
<outputDirectory>${basedir}/target/mapstore</
outputDirectory>
<encoding>UTF-8</encoding>
```

```
<resources>
           <resource>
               <directory>${basedir}/../web/client</directory>
               <includes>
                  <include>**/*.html</include>
                  <include>**/*.json</include>
                  <include>**/img/*</include>
                  <include>product/assets/symbols/*</include>
                  <include>**/*.less</include>
               </includes>
               <excludes>
                  <exclude>node modules/*</exclude>
                  <exclude>node_modules/**/*</exclude>
                   <exclude>**/libs/Cesium/**/*</exclude>
                  <exclude>**/test-resources/*</exclude>
               </excludes>
           </resource>
       </resources>
   </configuration>
</execution>
-<execution>
- <id>CesiumJS-navigation</id>
- <phase>process-classes</phase>
- <goals>
-
        <goal>copy-resources</goal>
- </goals>
- <configuration>
- <outputDirectory>${basedir}/target/mapstore/libs/
cesium-navigation</outputDirectory>
- <encoding>UTF-8</encoding>
- <resources>
     <resource>
- <directory>${basedir}/../web/client/libs/
cesium-navigation</directory>
- </resource>
- </resources>
- </configuration>
-</execution>
```

 remove all the external script and css related to cesium and cesiumnavigation now included as packages

```
-<script src="https://cesium.com/downloads/cesiumjs/releases/
1.42/Build/Cesium/Cesium.js"></script>
-<link rel="stylesheet" href="https://cesium.com/downloads/
cesiumjs/releases/1.42/Build/Cesium/Widgets/widgets.css" />
```

```
-<script src="libs/cesium-navigation/cesium-navigation.js"></
script>
-<link rel="stylesheet" href="libs/cesium-navigation/cesium-
navigation.css" />
```

• This step is needed only for custom project with a specific publicPath different from the default one. In this case you may need to specify what folder deliver the cesium build (by default dist/cesium). To do that, you can add the cesiumBaseUrl parameter in the webpack dev and prod configs to the correct location of the cesium static assets, widgets and workers folder.

# Migration from 2021.02.01 to 2021.02.02

## Style parsers dynamic import

The style parser libraries introduced a dynamic import to reduce the initial bundle size. This change reflects to the getStyleParser function provided by the VectorStyleUtils module. If a downstream project of MapStore is using getStyleParser it should update it to this new version:

```
// example
- // old use of parser
- const parser = getStyleParser('sld');
+ // new use of parser
+ getStyleParser('sld')
+    .then((parser) => {
+         // use parser
+     });
```

# Migration from 2021.02.00 to 2021.02.01

This update contains a fix for a minor vulnerability found in log4j library. For this reason you may need to update the dependencies of your project Note

This vulnerability **is not** CVE-2021-44228 but only a couple of smaller ones, that involve Log4J ( CVE-2021-44228 is for Log4J2 ). Anyway MapStore is not prone to these vulnerabilities with the default configuration. For more information, see the dedicated blog post

here the instructions:

#### Align pom.xml files

Here the changes in pom.xml and web/pom.xml to update:

- Change mapstore-backend into mapstore-services and set the version to 1.2.2

• Set geostore-webapp version to 1.7.1

• Set http\_proxy version to 1.1.1 (should already be there)

```
<dependency>
```

• Set print-lib version geosolutions-2.0 to version geosolutions-2.0.1

# Migration from 2021.01.04 to 2021.02.00

## Theme updates and CSS variables

The theme of MapStore has been updated to support CSS variables for some aspects of the style, in particular colors and font families. The web/client/ themes/default/variables.less file contains all the available variables described under the @ms-theme-vars ruleset. It is suggested to :

• update the lesscss variables in the projects because the variables starting with @ms2- will be deprecated soon:

```
@ms2-color-text -> @ms-main-color @ms2-color-background ->
@ms-main-bg @ms2-color-shade-lighter -> @ms-main-border-color
@ms2-color-code -> @ms-code-color
@ms2-color-text-placeholder -> @ms-placeholder-color
@ms2-color-disabled -> @ms-disabled-bg @ms2-color-text-disabled ->
@ms-disabled-color
```

```
@ms2-color-text-primary -> @ms-primary-contrast
```

@ms2-color-primary -> @ms-primary @ms2-color-info -> @ms-info @ms2color-success -> @ms-success @ms2-color-warning -> @ms-warning @ms2color-danger -> @ms-danger

• The font family has been update to Noto Sans so all the html need to be updated removing the previous font link with:

```
<link rel="preconnect" href="https://fonts.gstatic.com">
<link href="https://fonts.googleapis.com/css2?
family=Noto+Sans&display=swap" rel="stylesheet">
```

• if you are importing react-select or react-widgets inline css/less in your own project, you have to remove the import. Now the stile of these libraries is managed at project level

## Project system

During this release MapStore we started an rewrite of the project system, organized in different phases.

The first phase of this migration has been identified by this pull request. In this phase we are supporting the backward compatibility as much as possible, introducing the new project system in parallel with the new one (experimental). In the future the current script will be deprecated in favor of the new one.

Here below the breaking changes introduced in this release to support this new system:

This section will tell you how to migrate to support the following changes:

- Minor changes to prod-webpack.config.js
- Move front-end configuration files in configs folder
- Back-end has been reorganized

#### Minor changes to prod-webpack.config.js

Minor changes to prod-webpack.config.js:

```
diff --git a/project/standard/templates/prod-webpack.config.js

#### Move front-end configuration files in configs folder

We suggest you to move them as well from root to configs folder, and align your app.jsx configuration with the new standard (if you changed the location of configs). This will allow to use the data dir in an easy way. So:

- Move the following files in configs directory:
- localConfig.json
- new.json
- pluginsConfig.json
- config.json
- simple.json
- If changed something in app.jsx about configuration, align to get the files moved in config.
- To allow MapStore to copy the correct file in the final war, you have to change web/pom.xml execution copy-resources for id config files this way (this only if you didn't customized localConfig.json):

```
<goal>copy-resources</goal>
                </goals>
                    <goal>copy-resources</goal>
                </goals>
                    <configuration>
                         <outputDirectory>${basedir}/target/
__PROJECTNAME__/MapStore2/web/client</outputDirectory>
                         <outputDirectory>${basedir}/target/
+
__PROJECTNAME__/MapStore2/web/client/configs</outputDirectory>
                        <encoding>UTF-8</encoding>
                        <resources>
                            <resource>
                                 <directory>${basedir}/../
MapStore2/web/client</directory>
                                 <directory>${basedir}/../
MapStore2/web/client/configs</directory>
                                <includes>
                                    <include>localConfig.json</
include>
                                </includes>
```

#### Back-end has been reorganized

In particular:

- all the java code has been moved from web/src/ to the java/ and product/ directories (and release, already existing).
- mapstore-backend has been renamed into mapstore-services.
- Some servlets have been added in order to provide native support to data dir and make it work with the new configs directory.

So you will have to:

- Align the pom.xml to the latest versions of the libs
- Edit the web.xml and change the \*-servlet.xml files to expose the new services

Note

Future evolution of the project will avoid you to keep your own copies of the pom files as much as possible, reducing the boilerplate and making migration a lot easier. For this reasons these migration guidelines will change soon.

Here below the details of the changes.

ALIGN POM.XML FILES TO LATEST VERSIONS OF THE LIBS

Here the changes in pom.xml and `web/pom.xml to update:

- Change mapstore-backend into mapstore-services and set the version to 1.2.1

```
+ <version>1.2.1</version>
</dependency>
```

• Set geostore-webapp version to 1.7.0

• Set http\_proxy version to 1.1.0 (should already be there)

EDIT THE WEB.XML AND CHANGE THE \*-SERVLET.XML FILES TO EXPOSE THE NEW SERVICES

- Copy from mapstore to folder web/src/main/webapp/WEB-INF/ the files:
- configs-servlet.xml
- extensions-servlet.xml
- loadAssets-servlet.xml
- Remove the old dispatcher-servlet.xml (it has been replaced by loadAssets-servlet.xml for backward compatibility)
- Align web/src/main/webapp/WEB-INF/web.xml with the new servlets as changes below (remove dispatcher entry in favour of the following).

#### Data directory has been reorganized and is now available also for product

The new organization of the data directory is:

- configs will contain all json files (localConfig.json, new.json, pluginsConfig.json, ...) and all the .patch files applied to them.
- extensions folder contains all the data for the extensions, including extensions.json
- The root contains the properties files to configure database, proxy and other configs

To organize your old data directory accordingly to the new specification.

- Move all .json and .json.patch files in configs folder (except extensions.json)
- Move the directory dist/extensions to simply extensions .
- The file extensions.json have to be moved in extensions/ extensions.json.
- Edit the file extensions/extensions.json changing the paths from dist/ extensions/<Plugin-Name>/... to <Plugin-Name>/...

You can set it up by configuring datadir.location java system property. Changes to paths or configuration files are not required anymore.

#### Configurations

• Embedded now uses popup as default. Align localConfig.json plugins --> embedded --> Identify with the latest one:

```
{
    "name": "Identify",
    "cfg": {
        "showInMapPopup":true,
        "viewerOptions": {
            "container": "{context.ReactSwipe}"
        }
    }
}
```

# Migration from 2021.01.01 to 2021.01.03

Generally speaking this is not properly a breaking change, but more a fix to apply to your installations. Certificate for 'cesiumjs.org' has expired at 2021.05.05, so to continue using CesiumJS with MapStore you will have to replace all the URLs like https://cesiumjs.org/releases/1.17 in

https://cesium.com/downloads/cesiumjs/releases/1.17. This is the main fix of this minor release. See this pull request on GitHub as a sample to apply these changes to your project.

# Migration from 2021.01.00 to 2021.01.01

## Update embedded entry to load the correct configuration

Existing MapStore project could have an issue with the loading of map embedded page due to the impossibility to change some configuration such as localConfig.json or translations path in the javascript entry. This issue can be solved following these steps: 1 - add a custom entry named embedded.jsx in the js/ directory of the project with the content:

```
import {
   setConfigProp,
   setLocalConfigurationFile
} from '@mapstore/utils/ConfigUtils';
// Add custom (overriding) translations
// example for additional translations in the project folder
// setConfigProp('translationsPath', ['./MapStore2/web/client/
translations', './translations']);
setConfigProp('translationsPath', './MapStore2/web/client/
translations');
// __PROJECTNAME__ is the name of the project used in the
creation process
setConfigProp('themePrefix', '__PROJECTNAME__');
// Use a custom plugins configuration file
// example if localConfig.json is located in the root of the
project
// setLocalConfigurationFile('localConfig.json');
setLocalConfigurationFile('MapStore2/web/client/
```

localConfig.json');

```
// async load of the standard embedded bundle
import('@mapstore/product/embedded');
```

2 - update the path of the embedded entry inside the webpack.config.js and prod-webpack.config.js files with:

```
// __PROJECTNAME__ is the name of the project used in the
creation process
'__PROJECTNAME__-embedded': path.join(__dirname, "js",
"embedded"),
```

#### Locate plugin configuration

Configuration for Locate plugin has changed and it is not needed anymore inside the Map plugin

• old localConfig.json configuration needed 'locate' listed as tool inside the Map plugin and as a separated Locate plugin

```
// ...
{
    "name": "Map",
    "cfg": {
        "tools": ["locate"],
        // ...
    }
},
{
    "name": "Locate",
    // ...
}
// ...
```

• new localConfig.json configuration removes 'locate' from tools array and it keeps only the plugin configuration

```
// ...
{
    "name": "Map",
    "cfg": {
        // ...
    }
},
{
    "name": "Locate",
    // ...
}
// ...
```

# Update an existing project to include embedded Dashboards and GeoStories

Embedded Dashboards and GeoStories need a new set of javascript entries, html templates and configuration files to make them completely available in an existing project.

The steps described above assume this structure of the MapStore2 project for the files that need update:

```
MapStore2Project/
|-- ...
|-- js/
| |-- ...
    |-- dashboardEmbedded.jsx (new)
    |-- geostoryEmbedded.jsx (new)
|-- MapStore2/
|-- web/
   |-- ...
    |-- pom.xml
|-- ...
|-- dashboard-embedded-template.html (new)
|-- dashboard-embedded.html (new)
|-- ...
|-- geostory-embedded-template.html (new)
|-- geostory-embedded.html (new)
|-- ...
|-- prod-webpack.config.js
|-- ...
|-- webpack.config.js
```

1) create the entries files for the embedded application named dashboardEmbedded.jsx and geostoryEmbedded.jsx in the js/ folder with the

following content (see links): - dashboardEmbedded.jsx - geostoryEmbedded.jsx

2) add the html files and templates in the root directory of the project with these names and content (see links): - dashboard-embedded-template.html dashboard-embedded.html - geostory-embedded-template.html - geostoryembedded.html

3) update webpack configuration for development and production with the new entries and the related configuration:

```
- webpack.config.js
```js
module.exports = require('./MapStore2/build/buildConfig')(
    {
        // other entries...,
        // add new embedded entries to entry object
        "geostory-embedded": path.join(__dirname, "js",
"geostoryEmbedded"),
        "dashboard-embedded": path.join(__dirname, "js",
"dashboardEmbedded")
    },
   // ...
);
- prod-webpack.config.js
```is
module.exports = require('./MapStore2/build/buildConfig')(
    {
        // other entries...,
        // add new embedded entries to entry object
        "geostory-embedded": path.join(__dirname, "js",
"geostoryEmbedded"),
        "dashboard-embedded": path.join(__dirname, "js",
"dashboardEmbedded")
    },
    // ...
    [
        // new HtmlWebpackPlugin({ ... }),
        // add plugin to copy all the embedded html and inject
the correct bundle
        new HtmlWebpackPlugin( {
            template: path.join(__dirname, 'geostory-embedded-
template.html'),
            chunks: ['geostory-embedded'],
            inject: "body",
            hash: true,
            filename: 'geostory-embedded.html'
        }),
        new HtmlWebpackPlugin( {
            template: path.join(__dirname, 'dashboard-embedded-
template.html'),
            chunks: ['dashboard-embedded'],
            inject: 'body',
```

```
hash: true,
         filename: 'dashboard-embedded.html'
})
],
// ...
);
```

4) Add configuration to localConfig.json in the plugins section related to Share functionalities (Only with custom localConfig.json in the project): - Dashboard share configuration

```
```js
"dashboard": [
    // ...
    {
        "name": "Share",
        "cfg": {
            "showAPI": false,
            "advancedSettings": false,
            "shareUrlRegex": "(h[^#]*)#\\/dashboard\\/([A-Za-
z0-9]*)",
            "shareUrlReplaceString": "$1dashboard-
embedded.html#/$2",
            "embedOptions": {
                "showTOCToggle": false,
                "showConnectionsParamToggle": true
            }
       }
   },
    // ...
]
. . .
- Dashboard share configuration
```js
"geostory": [
    // ...
    {
        "name": "Share",
        "cfg": {
            "embedPanel": true,
            "showAPI": false,
            "advancedSettings": {
                "hideInTab": "embed",
                "homeButton": true,
                "sectionId": true
            },
            "shareUrlRegex": "(h[^#]*)#\\/geostory\\/([^\\/]*)\
\/([A-Za-z0-9]*)",
            "shareUrlReplaceString": "$1geostory-embedded.html#/
$3",
            "embedOptions": {
                "showTOCToggle": false
            }
       }
    },
    // ...
```

]

5) update the web/pom.xml to copy all the related resources in the final \*.war file with these new executions

```
<!-- __PROJECTNAME__ should be equal to the one in use in the</pre>
project, see other executions how they define the
outputDirectory path -->
<execution>
    <id>only dashboard-embedded.html</id>
    <phase>process-classes</phase>
    <goals>
        <goal>copy-resources</goal>
    </goals>
    <configuration>
        <outputDirectory>${basedir}/target/__PROJECTNAME__
outputDirectory>
        <encoding>UTF-8</encoding>
        <resources>
            <resource>
                <directory>${basedir}/../dist</directory>
                <includes>
                    <include>dashboard-embedded.html</include>
                </includes>
                <excludes>
                    <exclude>MapStore2/*</exclude>
                    <exclude>MapStore2/**/*</exclude>
                </excludes>
            </resource>
        </resources>
    </configuration>
</execution>
<execution>
    <id>only geostory-embedded.html</id>
    <phase>process-classes</phase>
    <goals>
        <goal>copy-resources</goal>
    </goals>
    <configuration>
        <outputDirectory>${basedir}/target/__PROJECTNAME__
outputDirectory>
        <encoding>UTF-8</encoding>
        <resources>
            <resource>
                <directory>${basedir}/../dist</directory>
                <includes>
                    <include>geostory-embedded.html</include>
                </includes>
                <excludes>
```

# Migration from 2020.02.00 to 2021.01.00

### Update to webpack 5 - Module federation

MapStore migrated to webpack 5 and provided the extension system using "Webpack Module Federation". Here the steps to update the existing files in your project.

### package.json:

- dev server scripts changed syntax. now you need to use webpack serve instead of webpack-dev-server. Replace also all --colors with --color in your scripts that use webpack / webpack-dev-server.
- Align dependencies and devDependencies with MapStore's one, reading the package.json, as usual.
- To support extensions in your project, you need to add ModuleFederationPlugin to your prod-webpack.config.js and webpack.config.js

```
const ModuleFederationPlugin = require('./MapStore/build/
moduleFederation').plugin; // <-- new line
module.exports = require('./buildConfig')(
    assign({
        "mapstore2": path.join(paths.code, "product", "app"),
        "embedded": path.join(paths.code, "product",
        "ms2-api": path.join(paths.code, "product", "api")
      },
      require('./examples')
      ),
      themeEntries,
      paths,
```

```
extractThemesPlugin,
 [extractThemesPlugin, ModuleFederationPlugin], // <-- this
 parameter has been changed, now it accepts also array of the
 plugins you want to add bot in prod and dev
```

Other the other changes required are applied automatically in buildConfig.js.

### Eslint config

Now eslint configuration is shared in a separate npm module. To update your custom project you have to remove the following files:

- .eslintignore
- .eslintconfig

And add to package.json the following entry, in the root:

If you have aproject that includes MapStore as a dependency, you can run npm run updateDevDeps to finalize the update. Otherwise make you sure to include:

- devDependencies:
- add "@mapstore/eslint-config-mapstore": "1.0.1",
- delete babel-eslint
- dependencies:
- update `"eslint": "7.8.1"

### App structure review

From this version some base components of MapStore App (StandardApp, StandardStore ...) has been restructured and better organized. Here a list of the breaking change you can find in a depending project

- web/client/product/main.jsx has been updated to new import and export syntax (removed require and exports.module). So if you are importing it (usually in your app.jsx) you have to use the import syntax or use require(...).default in your project. The same for the other files.
- New structure of arguments in web/client/stores/StandardStore.js

```
const appStore = (
    {
        initialState = {
            defaultState: {},
            mobile: {}
        },
        appReducers = {},
        appEpics = {},
        rootReducerFunc = ({ state, action, allReducers }) =>
allReducers(state, action)
        },
        plugins = {},
        storeOpts = {}
) {
```

- Moved standard epics, standard reducers and standard rootReducer function from web/client/stores/StandardStore.js to a separated file web/ client/stores/defaultOptions.js
- loading extensions functionalities inside StandardApp has been moved to an specific withExtensions HOC, so if you are not using main.js but directly StandardApp and you need extensions you need to add this HOC to your StandardApp

# Migration from 2020.01.00 to 2020.02.00

### New authentication rule for internal services

With this new version the support for uploading extensions has been introduced. A new entry point needs administration authorization to allow the upload of new plugins by the administrator. So:

• In localConfig.json add the following entry in the authenticationRules array:

```
{
    "urlPattern": ".*rest/config.*",
    "method": "bearer"
}
```

the final entry should look like this

```
"authenticationRules": [{
    "urlPattern": ".*geostore.*",
    "method": "bearer"
    }, {
        "urlPattern": ".*rest/config.*",
        "method": "bearer"
    }, ...],
```

### Translation files

 The translations file extension has been changed into JSON. Now translation files has been renamed from data.<locale> to data.<locale>.json. This change makes the .json extension mandatory for all translation files. This means that depending projects with custom translation files should be renabled in the same name. E.g. data.it-IT have to be renamed as data.it-IT.json

### **Database Update**

Database schema has changed. To update your database you need to apply this SQL scripts to your database

• Update the user schema run the script available here:

```
-- Update the geostore database from 1.4.2 model to 1.5.0
-- It adds fields to gs_security for external authorization
-- The script assumes that the tables are located into the
schema called "geostore"
-- if you put geostore in a different schema, please edit
the following search_path.
SET search_path TO geostore, public;
-- Tested only with postgres9.1
-- Run the script with an unprivileged application user allowed
to work on schema geostore
alter table gs_security add column username varchar(255);
alter table gs_security add column groupname varchar(255);
create index idx_security_username on gs_security (username);
create index idx_security_groupname on gs_security (groupname);
```

### Add new categories

```
-- New CONTEXT category
INSERT into geostore.gs_category (id ,name) values (
nextval('geostore.hibernate_sequence'), 'CONTEXT') ON CONFLICT
DO NOTHING;
-- New GEOSTORY category (introduced in 2020.01.00)
INSERT into geostore.gs_category (id ,name) values
(nextval('geostore.hibernate_sequence'), 'GEOSTORY') ON
CONFLICT DO NOTHING;
-- New TEMPLATE category
INSERT into geostore.gs_category (id ,name) values (
nextval('geostore.hibernate_sequence'), 'TEMPLATE') ON
CONFLICT DO NOTHING;
-- New USERSESSION category
INSERT into geostore.gs_category (id ,name) values (
```

```
nextval('geostore.hibernate_sequence'), 'USERSESSION') ON
CONFLICT DO NOTHING;
```

### Backend update

For more details see this commit

new files have been added:

- web/src/main/webapp/WEB-INF/dispatcher-servlet.xml
- web/src/main/resources/mapstore.properties

some files has been changed:

- web/src/main/webapp/WEB-INF/web.xml
- pom.xml
- web/pom.xml

# Migration from 2019.02.01 to 2020.01.00

With MapStore **2020.01.00** some dependencies that were previously hosted on github, have now been published on the npm registry, and package.json has been updated accordingly. Here is the PR that documents how to update local package.json and local webpack if not using the mapstore buildConfig/ testConfig common files.

After updating package.json run **npm install** Now you should be able to run locally with **npm start** 

For more info see the related issue

Moreover a new category has been added for future features, called GEOSTORY.

It is not necessary for this release, but, to follow the update sequence, you can add it by executing the following line.

```
INSERT into geostore.gs_category (id ,name) values
(nextval('geostore.hibernate_sequence'), 'GEOSTORY') ON
CONFLICT DO NOTHING;
```

# Migration from 2019.01.00 to 2019.01.01

MapStore **2019.01.01** changes the location of some of the build and test configuration files. This also affects projects using MapStore build files, sp if you update MapStore subproject to the **2019.01.01** version you also have to update some of the project configuration files. In particular:

- webpack.config.js and prod-webpack.config.js:
- update path to themes.js from ./MapStore2/themes.js to ./MapStore2/build/ themes.js
- update path to buildConfig from ./MapStore2/buildConfig to ./MapStore2/ build/buildConfig
- karma.conf.continuous-test.js and karma.config.single-run.js: update path to testConfig from ./MapStore2/testConfig to ./MapStore2/build/testConfig

# Migration from 2017.05.00 to 2018.01.00

MapStore **2018.01.00** introduced theme and js and css versioning. This allows to auto-invalidates cache files for each version of your software. For custom projects you could choose to ignore this changes by setting version: "no-version" in your app.jsx StandardRouter selector:

```
//...
const routerSelector = createSelector(state => state.locale,
(locale) => ({
    locale: locale || {},
    version: "no-version",
    themeCfg: {
        theme: "mythheme"
      },
      pages
}));
```

```
const StandardRouter = connect(routerSelector)(require('../
MapStore2/web/client/components/app/StandardRouter'));
//...
```

### Support js/theme versioning in your project

Take a look to this pull request as reference. Basically versioning is implemented in 2 different ways for css and js files :

- Add at build time the js files inclusion to the files, with proper hashes.
- Load theme css files appending to the URL the ?{version} where version is the current mapstore2 version The different kind of loading for css files is needed to continue supporting the theme switching capabilities. For the future we would like to unify these 2 systems. See this issue.

You have to:

- Add the version file to the root (version.txt).
- Create a template for each html file you have. These files will replace the html files when you build the final war file. These files are like the original ones but without the [bundle].js file inclusion and without theme css.
- Add HtmlWebpackPlugin for production only, one for each js file. This plugin will add to the template file the script inclusion (example).
- if you have to include the script in the head (e.g. api.html has some script that need the js to be loaded before executing the inline scripts), use the option inject: 'head'
- change each entry point (app.jsx, api.jsx, embedded.jsx, yourcoustomentrypoint.jsx) this way (example):
- version reducer in StandardRouter
- loadVersion action in initialActions
- version and loadAfterTheme selectors to StandardRouter state.

```
// Example
const {versionSelector} = require('../MapStore2/web/client/
selectors/version');
```

```
const {loadVersion} = require('../MapStore2/web/client/actions/
version');
const version = require('.../MapStore2/web/client/actions/
version');
//...
StandardRouter = connect ( state => ({
    locale: state.locale || {},
        pages,
        version : versionSelector(state),
        loadAfterTheme: loadAfterThemeSelector(state)
    }))(require('../MapStore2/web/client/components/app/
StandardRouter'))
const appStore = require('.../MapStore2/web/client/stores/
StandardStore').bind(null, initialState, {
    // ...
    version: version
});
// ...
const appConfig = {
   // ...
    initialActions: [loadVersion]
}
```

- Add to your pom.xml some execution steps to replace html files with the ones generated in 'dist' directory. (example). And copy version.txt
- Override the version file in your build process (e.g. you can use the commit hash)

# Migration from 2017.05.00 to 2017.03.00 and previews

In **2017.03.00** the createProject.js script created only a custom project. From version 2017.04.00 we changed the script to generate 2 kind of projects:

- custom: the previous version
- standard: mapstore standard

Standard project wants to help to generate a project that is basically the MapStore product, where you can add your own plugins and customize your theme (before this you had to create a project similar to MapStore on your own) Depending on our usage of custom project, this may introduce some breaking changes. If you previously included some file from product folder, now app.jsx has been changed to call main.jsx. Please take a look on how the main product uses this to migrate your changes inside your custom project.

# Migration from 2017.01.00 to 2017.02.00

The version 2017.02.00 has many improvements and changes:

- introduced redux-observable
- updated webpack to version 2
- updated react-intl to version 2.x
- updated react to [version 15.4.2] (https://facebook.github.io/react/blog/ 2016/04/07/react-v15.html)
- updated react-bootstrap to version 0.30.7

### We suggest you to:

- align your package.json with the latest version of 2017.02.00.
- update your webpack files (see below).
- update your tests to react 15 version. see upgrade guide
- Update your react-bootstrap custom components with the new one (see below).

### Side Effect Management - Introduced redux-observable

To manage complex asynchronous operations the thunk middleware is not enough. When we started with MapStore there was no alternative to thunk. Now we have some options. After a spike (results available here) we chose to use redux-observable. For the future, we strongly recommend to use this library to perform asynchronous tasks.

Introducing this library will allow to :

• remove business logic from the components event handlers

- now all new actionCreators should return pure actions. All async stuff will be deferred to the epics.
- avoid bouncing between components and state to trigger side effect
- speed up development with rxjs functionalities
- Existing thunk integration will be maintained since all the thunks will be replaced.

If you are using the Plugin system and the StandardStore, you may have only to include the missing new dependencies in your package.json (redux-observable and an updated version of redux).

Check the current package.json to get he most recent versions. For testing we included also redux-mockup-store as a dependency, but you are free to test your epics as you want.

For more complex integrations check this pull request to see how to integrate redux-observable or follow the guide on the redux-observable site.

### Webpack update to version 2

We updated webpack (old one is deprecated), check this pull request to find out how to update your webpack files. here a list of what we had to update:

- module.loaders are now module.rules
- update your package.json with latest versions of webpack, webpack plugins and karma libs and integrations (Take a look to the changes on package.json in the pull request if you want a detailed list of what to update in this case).
- change your test proxy configuration with the new one.

More details on the webpack site.

### react-intl update to 2.x

See this pull request for the details. You should only have to update your package.json

### react update to 15.4.2

Check this pull request to see how to:

- update your package.json
- update your tests

### React Bootstrap update

The version we are using is not documented anymore, and not too much compatible with react 15 (too many warnings). So this update can not be postponed anymore. The bigger change in this case is that the Input component do not exists anymore. You will have to replace all your Input with the proper components, and update the package.json. See this pull request for details.

# How to release

Below you can find the release procedure as a checklist. On each release it can be updated (if needed), copied and pasted into a GitHub issue, of course changing the release name. Then you can check each entry on the GitHub issue when done until the release is end.

# Changelog generation

Generate new changelog by running this:

```
npm run generate:changelog <oldReleaseNumber>
<newReleaseNumber>
```

```
# usage
# generate:changelog 2022.01.00 2022.02.00
```

# Release Checklist

### naming conventions

### release and tag

- vYYYY.XX.mm name of the release and tag. (e.g. v2022.01.01)
- YYYY is the year,
- **XX** is the incremental number of the release for the current year (starting from 01)
- **mm** is an incremental value (starting from 00) to increment for minor releases

### stable branch

• YYYY.XX.xx name of stable branch (e.g. 2022.01.xx )

- YYYY is the year
- **XX** is the incremental number of the release for the current year (starting from 01)
- xx is the fixed text xx

### Release procedure

## Setup and preliminary checks This steps have to be followed always when preparing a new release. - [ ] Create an issue with this checklist in the release milestone, named "Release YYYY.XX.mm". Create the milestone if it doesn't exist. (Name YYYY.XX.mm). - [] Verify if it is needed to release a new version of http\_proxy, mapfish-print or geostore, and do it if necessary. - [] for geostore, check if [here](https://maven.geosolutions.it/it/geosolutions/geostore/geostore-webapp/) is present the version specified in the [release calendar 2022] (https://github.com/geosolutions-it/MapStore2/wiki/MapStore-Releases-2022). (Geostore release procedure [here](https:// github.com/geosolutions-it/geostore/wiki/Release-Process) - [ ] for http\_proxy, check if [here](https:// mvnrepository.com/artifact/proxy/http\_proxy) is present the version specified in the [release calendar 2022](https:// github.com/geosolutions-it/MapStore2/wiki/MapStore-Releases-2022) ## New major branch creation If major release (YYYY.XX.00) follow these sub-steps: - [ ] create a branch `YYYY.XX.xx` from master branch (`xx` is really `xx`, example: 2018.01.xx). This is the new \*\*stable branch\*\* - [] Change [MapStore2-QA-Build](http:// build.geosolutionsgroup.com/view/MapStore/job/MapStore/view/ MapStore%20QA/job/MapStore2-QA-Build/) by updating the `branch` parameter in the build configuration page to `YYYY.XX.xx` - [ ] on MapStore \*\*stable branch\*\* - [ ] Fix `pom.xml` files to make sure that no -SNAPSHOT \*\*dependencies\*\* are used anymore. - [ ] on MapStore \*\*master branch\*\*

- [ ] increase version of java modules. (`mvn versions:set -DnewVersion=<SNAPSHOT\_VERSION> -DprocessAllModules -DgenerateBackupPoms=false`). Where `<SNAPSHOT\_VERSION>` increases the major number. (e.g. `1.3-SNAPSHOT` --> `1.4-SNAPSHOT`)

- [ ] Manually update project pom templates to use `mapstore-services` of `<SNAPSHOT\_VERSION>` to the new one. (`projects/templates/web/pom.xml`).

- [ ] Increment version of `package.json` on master
\*\*0.<x-incremented&gt;.0\*\*

[] Create on [ReadTheDocs](https://readthedocs.org/projects/mapstore/) project the version build for `YYYY.XX.xx` (click on "Versions" and activate the version of the branch)
[] create a branch with the same name (`YYYY.XX.xx`) in [MapStoreExtension](https://github.com/geosolutions-it/MapStoreExtension) repository.

#### ## Before the Release

- [ ] Check `pom.xml` dependencies are all in fixed stable versions ( no `-SNAPSHOT` usage release).

- [ ] Check that MapStoreExtension repository is aligned and working

- [ ] Make sure that the issues of the current release are connected to the current milestone on github.

- [ ] Test on QA [https://qa-mapstore.geosolutionsgroup.com/ mapstore/](https://qa-mapstore.geosolutionsgroup.com/mapstore/)

- [ ] Test \*\*everything\*\*, not only the new features

- [ ] Test the creation of a standard project starting in from the stable branch and with the internal backend, so `npm start:app`, then check that an empty homepage loads correctly

- [ ] Test [Binary](http://build.geosolutionsgroup.com/view/ MapStore/job/MapStore/view/MapStore%20QA/job/MapStore2-QA-Build/) (take the mapstore2-<RELEASE\_BRANCH>-qa-bin.zip, from latest build)

The following procedure allow you to migrate issues from zenhub release to github milestone.

assign the label "current-release" to all the issues and PRs of the current zenhub release
use the label to filter the issues on github and assign to all the issues and Prs the milestone created
remove assignments of "current-release"

#### ## Release

- [ ] on \*\*master branch\*\* do and merge a PR for updating: - [ ] \*\*Only on major release\*\* `stableBranch` in particular the `utility/projects/projectLib.js` file and commit (used in `createProject.js`)

- [ ] Update `CHANGELOG.md` [Instructions](https://
mapstore.readthedocs.io/en/latest/developer-guide/release/
#changelog-generation)

- [ ] On \*\*stable\*\* branch, do and merge a PR for updating:

- [ ] \*\*Only on major release\*\* `stableBranch` in particular the `utility/projects/projectLib.js` file (used in `createProject.js`)

- [ ] Update `CHANGELOG.md` [Instructions](https://
mapstore.readthedocs.io/en/latest/developer-guide/release/
#changelog-generation)

- [] Update the version of java modules on the stable branch to a stable, incremental version. Run `mvn versions:set -DnewVersion=<SNAPSHOT\_VERSION> -DprocessAllModules -DgenerateBackupPoms=false` to update package version, where `<VERSION>` is the version of the java packages (e.g. `1.3.1`). (`mvn:release:prepare` may also work. TODO: check this command)

- [ ] Manually update project pom templates to use `mapstoreservices` of `<VERSION>`. `project/standard/templates/web/ pom.xml`

- [ ] Release a stable `mapstore-services` and `mapstore-webapp`

- [] Run `mvn clean install deploy -f java/pom.xml` to deploy `mapstore-services` and `mapstore-webapp` on maven.geosolutions.it .

#### ## MapStore Stable deploy

- [ ] check if there are changes to be ported to STABLE branch of [mapstore-datadir](https://github.com/geosolutions-it/ mapstore-datadir/tree/STABLE) repo

- [] if so prepare a PR to be merged

- [ ] merge the PR and move on with the steps otherwise stop here

- [ ] Launch the [MapStore2-Stable-Build](http:// build.geosolutionsgroup.com/view/MapStore/job/MapStore/view/ MapStore%20Stable/job/MapStore2-Stable-Build/) and wait for the MapStore2-Stable-EndPointsTests to complete as well

- [ ] When previous two jobs are green you can:

- [] Lunch [MapStore2-Stable-Build](http://

build.geosolutionsgroup.com/view/MapStore/job/MapStore/view/ MapStore%20QA/job/MapStore2-Stable-Build/)

- [ ] `branch` build on stable branch `YYYY.XX.xx`

- [ ] `version`: `YYYY.XX.mm`

- [ ] After "MapStore2-Stable-Build" finished, Launch [MapStore2-Stable-Deploy](http://build.geosolutionsgroup.com/ view/MapStore/job/MapStore/view/MapStore%20Stable/job/MapStore2-Stable-Deploy/) to install the latest stable version on official demo

- [ ] test the change has been applied, login on https://

mapstore.geosolutionsgroup.com and verify that the layers from `gs-stable` are visible without errors (typically authentication errors that was caused by the wrong auth-key).

## Build and publishing release

- [ ] Create a [github draft release](https://github.com/ geosolutions-it/MapStore2/releases)

- [ ] `branch` \*\*YYYY.XX.xx\*\*

- [ ] `tag` \*\*vYYYY.XX.mm\*\* (create a new tag from UI after entering this value)

- [ ] `release` name equal to tag \*\*vYYYY.XX.mm\*\*

- [ ] `description` describe the major changes and add links of the Changelog paragraph.

- [] Launch [MapStore2-Stable-Releaser](http://

build.geosolutionsgroup.com/view/MapStore/job/MapStore/view/ MapStore%20Stable/job/MapStore2-Stable-Releaser/) Jenkins job with \*\*YYYY.XX.mm\*\* for the version and \*\*YYYY.XX.xx\*\* for the branch to build and \*\*wait the end\*\*). \*\*Note:\*\* Using the MapStore2 Releaser allows to write the correct version number into the binary packages. In the overview of this job you can find and download :

- [ ] the latest `mapstore.war`
- [ ] the latest binary `mapstore2-YYYY.XX.mm-bin.zip`
- [] the printing bundle `mapstore-printing.zip`
- [ ] Upload to draft release
  - [ ] the updated binary `mapstore2-YYYY.XX.mm-bin.zip`
  - [ ] the `mapstore.war` package
  - [ ] `mapstore-printing.zip` on github release

- [ ] Publish the release

- [ ] create on [ReadTheDocs](https://readthedocs.org/projects/ mapstore/) project the version build for `vYYYY.XX.mm` (click on "Versions" and activate the version of the tag, created when release was published)

#### ## Build and publish MapStoreExtension release

- [ ] [Create a draft release](https://github.com/geosolutionsit/MapStoreExtension/releases/new) for [MapstoreExtension] (https://github.com/geosolutions-it/MapStoreExtension) with the same name and tag

- [ ] target of the release is \*\*stable branch\*\* aligned to latest commit in stable branch of main mapstore repo

- [ ] tag is \*\*vYYYY.XX.mm\*\*

- [ ] Update revision of mapstore to the release tag
\*\*vYYYY.XX.mm\*\*

- [ ] [run the build](https://github.com/geosolutions-it/ MapStoreExtension#build-extension) locally and attach to the

```
release the file `SampleExtension.zip` from the `/dist` folder
  - [ ] create a PR for the changes of the revision to the
MapstoreExtension repo
 - [] Merge the PR
  - [ ] Publish the release
  - [ ] Link the MapStore extension release in the MapStore
release
## Finalize Release
- [ ] Prepare a PR MapStore **stable branch** **YYYY.XX.xx** in
order to :
    - [ ] reset versions of java modules to `-SNAPSHOT` (`mvn
versions:set -DnewVersion=<SNAPSHOT_VERSION> -
DprocessAllModules -DgenerateBackupPoms=false`) where
`<SNAPSHOT_VERSION>` is the version to set. (e.g. 1.2-
SNAPSHOT).
    - [ ] Manually update project pom templates to use
`mapstore-services` of `<SNAPSHOT_VERSION>`. `project/standard/
templates/web/pom.xml`
    - [ ] on `package.json` increasing the minor "version"
number. **0.x.<number-of-minor-version&gt;**
- [ ] Write to the mailing list about the current release news
and the next release major changes
- [] Optional - prepare a PR for updating release procedure,
if needed
- [ ] Close this issue
- [ ] Close the related milestone **YYYY.XX.mm**
```

# Developer Generic Guidelines

This guide wants to provide general information and suggestions about how to write code for MapStore. It contains a practical guide to write plugins for MapStore, then some general information about writing redux actions, reducers and redux-observble epics, with some hints specific of MapStore.

Still to do:

- Writing enhancers
- Writing components
- Using JS API

Work in progress:

Extensions

# Creating a MapStore2 plugin

The MapStore2 plugins architecture allows building your own independent modules that will integrate seamlessly into your project.

Creating a plugin is like assembling and connecting several pieces together into an atomic module. This happens by writing a plugin module, a ReactJS JSX file exporting the plugin descriptor.

# Introduction

During this tutorial, you will learn how to create and configure plugins in a MapStore project. If you don't know how to work with MapStore projects, please read the Projects Guide. For this tutorial, a "standard project" is used.

# A plugin example

js/plugins/Sample.jsx

Plugins are react component exported with the createPlugin function

```
import React from "react";
import { createPlugin } from "@mapstore/utils/PluginsUtils";
const Sample = () => {
    const style = {
        position: "absolute",
        top: 100,
        left: 100,
        zIndex: 2000
    };
    return (
        <div style={style}>
            Sample
        </div>
    );
};
```

```
export default createPlugin("Sample", {
    component: Sample
});
```

Being a component with a name (**Sample** in our case) you can include it in your project by creating a *plugins.js* file.

```
js/plugins.js
```

```
import SamplePlugin from "./plugins/Sample";
export const plugins = {
    // ...
    SamplePlugin,
    // ...
};
export default {
    plugins
};
```

**Note** The chosen component name is always suffixed with **Plugin** when imported in the *plugins.js* file.

Include the plugin.js from your app.jsx either replacing the plugins import from the product or extending it:

js/app.jsx

```
...
import m2Plugins from "@mapstore/product/plugins";
import customPlugins from "./plugins";
import main from "@mapstore/product/main";
const allPlugins = {
    ...m2Plugins,
    plugins: {
        ...customPlugins.plugins,
        ...m2Plugins.plugins
    }
};
```

```
main(appConfig, allPlugins);
```

Then you have to configure it properly so that is enabled in one or more application modes / pages:

localConfig.json

```
{
    ...
    "plugins": {
        "desktop": [{ "name": "Sample" }, ...],
        ...
    }
}
```

Note: to enable a plugin you need to do two things:

- import it in the plugins.js file
- configure it in localConfig.json (remove the Plugins suffix here)

If one is missing, the plugin won't appear. To globally remove a plugin from your project the preferred way is removing it from plugins.js, because this will reduce the global javascript size of your application.

You can also specify plugins properties in the configuration, using the **cfg** property:

```
localConfig.json (2)
```

```
{
    ...
    "plugins": {
        "desktop": [{
            "name": "Sample",
            "cfg": {
                "myproperty": "myvalue"
            }
        }, ...],
        ...
```

# }

### A store connected plugin example

A plugin component is a **smart component** (connected to the Redux store) so that properties can be taken from the global state, as needed.

```
js/plugins/Sample.jsx (1)
  import React from "react";
  import { connect } from "react-redux";
  import PropTypes from "prop-types";
  import { createPlugin } from "@mapstore/utils/PluginsUtils";
  const SampleComponent = ({
      style,
      zoom
  }) => {
      return (
          <div style={style}>
              Zoom: {zoom}
          </div>
      );
  };
  SampleComponent.propTypes = {
      style: PropTypes.object,
      zoom: PropTypes.number
  };
  SampleComponent.defaultProps = {
      style: {
          position: "absolute",
          top: 100,
          left: 100,
          zIndex: 2000
      }
  };
  const Sample = connect((state) => {
      return {
          // connected property
```

```
zoom: state?.map?.present?.zoom
};
})(SampleComponent);
export default createPlugin("Sample", {
    component: Sample
});
```

A plugin can use actions to update the global state.

js/plugins/Sample.jsx (2)

```
import React from "react";
import { connect } from "react-redux";
import PropTypes from "prop-types";
import { createPlugin } from "@mapstore/utils/PluginsUtils";
import { changeZoomLevel } from "@mapstore/actions/map";
const SampleComponent = ({
   style,
   zoom,
   onZoom
}) => {
    return (
        <div style={style}>
            Zoom: {zoom}
            <br/><button onClick={() => onZoom(zoom + 1)}>
                Increase
            </button>
        </div>
    );
};
SampleComponent.propTypes = {
    style: PropTypes.object,
    zoom: PropTypes.number,
    onZoom: PropTypes.func
};
SampleComponent.defaultProps = {
    style: {
        position: "absolute",
        top: 100,
        left: 100,
        zIndex: 2000
```

```
},
onZoom: () => {}
};
const Sample = connect((state) => {
  return {
    zoom: state?.map?.present?.zoom
    };
}, {
    // connected action
    onZoom: changeZoomLevel
})(SampleComponent);
export default createPlugin("Sample", {
    component: Sample
});
```

A plugin can define its own state fragments and the related reducers. You will also be able to define your own actions.

js/actions/sample.js

```
export const UPDATE_SOMETHING = "SAMPLE:UPDATE_SOMETHING";
export const updateSomething = (payload) => ({
    type: UPDATE_SOMETHING,
    payload
});
```

js/reducers/sample.js

```
import { UPDATE_SOMETHING } from "@js/actions/sample";
function sample(
    state = { text: "Initial Text" },
    action
) {
    switch (action.type) {
        case UPDATE_SOMETHING:
            return {
                text: action.payload
            };
        default:
            return state;
    }
```

```
}
export default sample;
```

```
js/plugins/Sample.jsx (3)
```

```
import React from "react";
import { connect } from "react-redux";
import PropTypes from "prop-types";
import { createPlugin } from "@mapstore/utils/PluginsUtils";
import { updateSomething } from "@js/actions/sample";
import sample from "@js/reducers/sample";
const SampleComponent = ({
    style,
   text,
   onUpdate
}) => {
    return (
        <div style={style}>
           Text: {text}
            <button
                onClick={() => onUpdate("Updated Text")}
            >
            Update
            </button>
        </div>
    );
};
SampleComponent.propTypes = {
    style: PropTypes.object,
    text: PropTypes.string,
    onUpdate: PropTypes.func
};
SampleComponent.defaultProps = {
    style: {
        position: "absolute",
        top: 100,
        left: 100,
        zIndex: 2000
    },
    text: "",
    onUpdate: () => {}
```

```
};
const Sample = connect((state) => {
   return {
        // connected property
        text: state?.sample?.text
    };
}, {
   // connected action
    onUpdate: updateSomething
})(SampleComponent);
export default createPlugin("Sample", {
    component: Sample,
    reducers: {
        sample
    }
});
```

# Data fetching and side effects

Side effects should be limited as much as possible, but there are cases where a side effect cannot be avoided. In particular we need to asynchronously load the data from external web services or files.

To handle data fetching a plugin can define Epics. To have more detail about epics look at the Epics developers guide section of this documentation.

js/actions/sample.js

```
// custom action
export const LOAD_DATA = "SAMPLE:LOAD_DATA";
export const LOADED_DATA = "SAMPLE:LOADED_DATA";
export const LOAD_ERROR = "SAMPLE:LOAD_ERROR";
export const loadData = () => ({
   type: LOAD_DATA
});
export const loadedData = (payload) => ({
   type: LOADED_DATA,
   payload
});
```

```
export const loadError = (error) => ({
   type: LOAD_ERROR,
   error
});
```

js/reducers/sample.js

```
import { LOADED_DATA, LOAD_ERROR } from "@js/actions/sample";
function sample(
   state = { text: "Initial Text" },
   action
) {
   switch (action.type) {
       case LOADED_DATA:
            return {
               text: action.payload
            };
       case LOAD_ERROR:
           return {
               error: action.error
            };
       default:
           return state;
   }
}
export default sample;
```

js/epics/sample.js

```
import { Observable } from "rxjs";
import axios from "axios";
import {
   LOAD_DATA,
   loadedData,
   loadError
} from "@js/actions/sample";
export const loadDataEpic = (action$) =>
   action$.ofType(LOAD_DATA)
   .switchMap(() => {
       return Observable.defer(() =>
            axios.get("version.txt")
            )
```

js/plugins/Sample.jsx

```
import React from "react";
import { connect } from "react-redux";
import PropTypes from "prop-types";
import { createPlugin } from "@mapstore/utils/PluginsUtils";
import { loadData } from "@js/actions/sample";
import sampleEpics from "@js/epics/sample";
import sample from "@js/reducers/sample";
const SideEffectComponent = ({
   style,
   text,
   onLoad
}) => {
    return (
        <div style={style}>
            Text: {text}
            <button onClick={() => onLoad()}>
                Load
            </button>
        </div>
    );
};
SideEffectComponent.propTypes = {
    style: PropTypes.object,
    text: PropTypes.string,
```

```
onLoad: PropTypes.func
};
SideEffectComponent.defaultProps = {
    style: {
        position: "absolute",
       top: 100,
       left: 100,
        zIndex: 2000
    },
    text: "",
    onLoad: () => {}
};
const Sample = connect((state) => {
    return {
        text: state?.sample?.text
    };
}, {
   // connected action
    onLoad: loadData
})(SideEffectComponent);
export default createPlugin("Sample", {
    component: Sample,
    reducers: {
        sample
    },
    epics: sampleEpics
});
```

# **Plugin Containers**

It is possible to define **Container** plugins, that are able to receive a list of *items* from the plugins system automatically. Think of menus or toolbars that can dynamically configure their items / tools from the configuration.

In addition to those "user defined" containers, there is always a **root container**. When no container is specified for a plugin, it will be included in the root container.

```
js/plugins/Container.jsx
```

```
import React from "react";
import PropTypes from "prop-types";
import { createPlugin } from "@mapstore/utils/PluginsUtils";
const Container = ({
   style,
   items
}) => {
    return (
        <div style={style}>
            {items.map(item => {
                // item.plugin is the plugin ReactJS component
                const Item = item.plugin;
                return (
                    <Item
                        key={item.id}
                        id={item.id}
                        name={item.name}
                    />
                );
            })}
        </div>
    );
};
Container.propTypes = {
    style: PropTypes.object,
    items: PropTypes.array
};
Container.defaultProps = {
    style: {
        position: "absolute",
        top: 100,
        left: 100,
        zIndex: 2000
    },
    items: []
};
export default createPlugin("Container", {
    component: Container
});
```

## Plugins for other plugins

Since we have containers, we can build plugins that can be contained in one or more container plugins.

```
js/plugins/Sample.jsx
```

```
import React from "react";
import { connect } from "react-redux";
import PropTypes from "prop-types";
import { createPlugin } from "@mapstore/utils/PluginsUtils";
import sample from "@js/reducers/sample";
const SampleComponent = ({
   text
}) => {
   return (
       <div>
           Text: {text}
        </div>
    );
}:
SampleComponent.propTypes = {
   text: PropTypes.string
};
SampleComponent.defaultProps = {
   text: ""
};
const Sample = connect((state) => {
    return {
        text: state?.sample?.text
    };
})(SampleComponent);
export default createPlugin("Sample", {
    component: Sample,
    reducers: {
        sample
    },
    containers: {
        // we support the previously defined Container Plugin
```

```
as a
    // possible container for this plugin
    Container: {
        name: "Sample",
        id: "sample-tool",
        priority: 1
     }
  });
```

Each section defines a possible container for the plugin, as the name of another plugin (*Container* in the example). The properties in it define the plugin behaviour in relation to the container (e.g. id of the item).

Containers will receive a list of items similar to this:

```
items = [{ plugin: Sample, name: "Sample", id: "sample-
tool", ... }]
```

Notice that also container related properties can be overridden in the application configuration, using the override property:

localConfig.json

# **Plugins Configuration**

We have already mentioned that plugins can be configured through the localConfig.json file. The simplest configuration needed to include the plugin in a particular application mode is accomplished by listing a JSON object specifying the **name** property of the plugin in the plugins array of the chosen mode/page:

```
localConfig.json
```

```
{
    ...
    "plugins": {
        "desktop": [{ "name": "Sample" }, ...],
        ...
    }
}
```

It is possible to customize a plugin configuration adding a **cfg** property to the plugin JSON object. All the **cfg** properties are passed as props to the main component of the plugin.

### Dynamic configuration

Configuration can also dynamically change when the application state changes. This is accomplished by using expressions in configuration values. An expression is a value of the following form:

```
"property": "{expression}"
```

The expression itself is javascript code (supported by the browser, babel transpiled code is not supported here) where you can use the following variables:

- request: request URL parsed by the url library
- context: anything defined in plugins.js requires section
- *state*: a function usable to extract values from the **application state** (e.g. state('map.present.zoom' to get current zoom))

Note that not all the application state is available through the state function, only the *monitored state* is. To add new fragments the monitored state, you can add the following to localConfig.json:

```
{
    ...,
    "monitorState": [
        {"name": "router", "path": "router.location.pathname"},
        {"name": "browser", "path": "browser"},
        {"name": "featuregridmode", "path": "featuregrid.mode"}
],
    ...
}
```

The default monitored state is:

```
{
    ...,
    "monitorState": [
        {"name": "router", "path": "router.location.pathname"},
```

```
{"name": "browser", "path": "browser"},
    {"name": "geostorymode", "path": "geostory.mode"},
    {"name": "featuregridmode", "path": "featuregrid.mode"},
    {"name": "userrole", "path": "security.user.role"},
    {"name": "printEnabled", "path": "print.capabilities"}
],
....
}
```

#### Example

### Container configuration

Each plugin can define a list of supported containers, but it's the plugin system that decides which ones will be used at runtime based on:

- container existence: if a container is not configured, it will not be used
- between the existing ones, the ones with the highest priority property value will be chosen; note that a plugin can be included in more than one container if they have the same priority

#### Example

// ...

```
import { createPlugin } from "@mapstore/utils/PluginsUtils";
// ...
export default createPlugin("Sample", {
    component: Sample,
    containers: {
        Container1: {
            name: "Sample",
            id: "sample-tool",
            priority: 1,
            // ...
        },
        Container2: {
            name: "Sample",
            id: "sample-tool",
            priority: 2,
            // ...
        },
        Container3: {
            name: "Sample",
            id: "sample-tool",
            priority: 3,
            // ...
        }
    }
});
```

If all the containers exist, Container3 will be chosen, the one with highest priority, if not Container2 will be used, and so on.

To explicitly configure plugins containment and introduce custom behaviours (overriding default properties), the **override** configuration property is available. Using it, you can override the relation between a plugin and its supported containers.

We can change containers relation like this:

```
{
    ...,
    "plugins": {
        "desktop": [{
            "name": "Sample",
            "override": {
                "Container1": {
                "Container1"
                "Container1": {
                 "
```

```
"name": "custom name",
"priority": 4
}
...
}, ...],
...
}
...
```

This will force the plugin system to choose Container1 instead of Container3, and will override the name property.

There is also a set of options to (dynamically) add/exclude containers:

- **showin**: can be used to add a plugin to a container or more than one, in addition to the default one (it is an array of container plugin names)
- hideFrom: can be used to exclude a plugin from a given container or more than one (it is an array of container plugin names)
- doNotHide: can be used to show a plugin in the root container, in addition to the default one
- **alwaysRender**: can be used to always renders the component in the given container, regardless the priority

Note that also these properties accept dynamic expressions.

js/plugins/Container.jsx

```
import React from "react";
import PropTypes from "prop-types";
import { createPlugin } from "@mapstore/utils/PluginsUtils";
const Container = ({
    items
}) => {
    const style = {
        zIndex: 1000,
        border: "solid black 1px",
        width: "200px",
```

```
height: "200px",
        position: "absolute",
        top: "100px",
        left: "100px"
    };
    return (
        <div style={style}>
            {items.map(item => {
                // item.plugin is the plugin ReactJS component
                const Item = item.plugin;
                return (
                    <Item
                        key={item.id}
                        id={item.id}
                        name={item.name}
                    />
                );
            })}
        </div>
   );
};
Container.propTypes = {
    items: PropTypes.array
};
Container.defaultProps = {
   items: []
};
export default createPlugin("Container", {
   component: Container
});
```

js/plugins/ContainerOther.jsx

```
import React from "react";
import PropTypes from "prop-types";
import { createPlugin } from "@mapstore/utils/PluginsUtils";
const ContainerOther = ({
    items
}) => {
    const style = {
        zIndex: 1000,
```

```
border: "solid red 1px",
        width: "200px",
        height: "200px",
        position: "absolute",
        top: "100px",
        left: "100px"
    };
    return (
        <div style={style}>
            {items.map(item => {
                // item.plugin is the plugin ReactJS component
                const Item = item.plugin;
                return (
                    <Item
                        key={item.id}
                        id={item.id}
                        name={item.name}
                    />
                );
            })}
        </div>
    );
};
ContainerOther.propTypes = {
    items: PropTypes.array
};
ContainerOther.defaultProps = {
    items: []
};
export default createPlugin("ContainerOther", {
    component: ContainerOther
});
```

```
js/plugins/Sample.jsx
```

```
export default createPlugin("Sample", {
    component: Sample,
    containers: {
        Container: {
            name: "Sample",
            id: "sample-tool",
            priority: 1
        },
        ContainerOther: {
            name: "Sample",
            id: "sample-tool",
            priority: 1
        },
        j
    }
});
```

With this configuration the sample plugin will be shown in both Container and ContainerOther plugins (they have the same priority, so both are picked).

We can change this using showIn or hideFrom in localConfig.json:

localConfig.json - showIn and hideFrom examples

```
{
    ...,
    "plugins": {
        "desktop": [{
            "name": "Sample",
            "showIn": ["Container"]
            ...
        }, ...],
        ...
    }
    ...
}
```

```
or
```

```
{
...,
"plugins": {
"desktop": [{
```

```
"name": "Sample",

"hideFrom": ["ContainerOther"]

...

}, ...],

...

}

...

}
```

We can also add the plugin to the root container, using the doNotHide property (note that this is a container property, so we have to use an override for it):

localConfig.json - doNotHide example

```
{
    . . . ,
    "plugins": {
         "desktop": [{
             "name": "Sample",
             "showIn": ["Container"],
             "override": {
                  "Container": {
                      "doNotHide": true
                  }
             }
             . . .
        }, ...],
         . . .
    }
    . . .
}
```

Conditionally disabling plugins

Dynamic expression can also be used to enable a plugin only when a specific application state is met, using the **disablePluginIf** property.

```
{

...,

"plugins": {

"desktop": [{

"name": "Sample",
```

```
"cfg": {
    "disablePluginIf": "{state('mapType') ===
'cesium'}"
    }
    ...
    }, ...],
    ...
  }
  ...
}
```

The plugin will be disabled in 3D mode.

## Lazy loading plugins

You can lazy load your plugins components using the react lazy and Suspense API. This is especially useful for plugins that include components with big external libraries.

```
js/plugins/Sample.jsx
```

```
import React, { useState, lazy, Suspense } from "react";
import { createPlugin } from "@mapstore/utils/PluginsUtils";
const LazySampleComponent = lazy(() => import("@js/components/
LazySampleComponent"));
const Sample = () => {
    // this local state could be moved to redux state
    // as explained in previous sections
    const [enabled, setEnabled] = useState(false);
    const style = {
       position: "absolute",
       top: 100,
       left: 100
       zIndex: 2000
    };
    return (
       <div style={style}>
            <button onClick={() => setEnabled(enabled)}>Load
plugin</button>
            {enabled
                ? <Suspense fallback="Loading...">
                    <LazySampleComponent />
```

```
</Suspense>

: null}

</div>

);

};

export default createPlugin("Sample", {

component: Sample

});
```

# Testing plugins

As we already mentioned a plugin is a collection of entities that should already have unit tests (components, reducers, actions, selectors, epics). We can limit plugins testing to testing the interactions between these different entities, for example:

- connection of the redux state to the plugins properties
- epics that are related to the plugin lifecycle
- containment relations between plugins

To ease writing a plugin unit test, an helper is available (pluginsTestUtils) that can be used to:

- create a plugin connected with a redux store (**getPluginForTest**), initialized with plugin's defined reducers and epics, and with a given initial state
- get access to the redux store
- get access to the list of actions dispatched to the store
- get access to the list of containers plugins supported by the plugin (you can limit this list by passing your plugins definitions to getPluginForTest)

### Examples

js/plugins/\_\_tests\_\_/MyPlugin-test.js

```
import expect from "expect";
import React from "react";
import ReactDOM from "react-dom";
import MyPlugin from "../MyPlugin";
import { getPluginForTest } from "@mapstore/plugins/__tests__/
pluginsTestUtils";
const initialState = {};
describe("MyPlugin Test", () => {
    beforeEach((done) => {
        document.body.innerHTML = "<div id=\"container\"></</pre>
div>":
        setTimeout(done);
    });
    afterEach((done) => {
ReactDOM.unmountComponentAtNode(document.getElementById("container
        document.body.innerHTML = "";
        setTimeout(done);
    });
    it("creates MyPlugin with default configuration", () => {
        const {Plugin, store, actions, containers } =
getPluginForTest(MyPlugin, initialState);
        ReactDOM.render(<Plugin />,
document.getElementById("container"));
        expect(document.getElementById("<my plugin</pre>
id>")).toBeTruthy();
        expect(...);
    });
    // use pluginCfg to override plugins properties
    it("creates MyPlugin with custom configuration", () => {
        const {Plugin, store, actions, containers } =
getPluginForTest(MyPlugin, initialState);
        ReactDOM.render(<Plugin pluginCfg={{</pre>
            property: "value"
        }}/>, document.getElementById("container"));
        expect(document.getElementById("<my plugin</pre>
id>")).toBeTruthy();
        expect(...);
    });
    // test connected epics looking at the actions array
    it("test plugin epics", () => {
        const {Plugin, store, actions, containers } =
```

```
getPluginForTest(MyPlugin, initialState);
        ReactDOM.render(<Plugin/>,
document.getElementById("container"));
        store.dispatch({
            type: ACTION_CAPTURED_BY_AN_EPIC,
            payload
        });
        expect(actions.filter(action => action.type ===
ACTION_LAUNCHED_BY_AN_EPIC).length).toBe(1);
    });
    // test supported containers
    it("test containers", () => {
        const {Plugin, store, actions, containers } =
getPluginForTest(MyPlugin, initialState, {
            MyContainerPlugin: {}
        });
        ReactDOM.render(<Plugin/>,
document.getElementById("container"));
expect(Object.keys(containers)).toContain("MyContainer");
    });
});
```

## General Guidelines

### Components

- Define the plugin component(s) into dedicated JSX file(s), so that they can be reused outside of the plugin
- · Connect the component(s) in the plugin JSX file

### State

• Define your own state fragment (and related actions and reducers) to handle internal state, and use existing actions and state fragments from MapStore2 to interact with the framework

### Selectors

• Use existing selectors when possible to connect the state, eventually using reselect to compose them together or with your own selectors

### General

- Avoid as much as possible direct interactions between different plugins; plugins are meant to be independent modules, so they should be able to work if other plugins appear / disappear from the application configuration
- Interact with other plugins and the application itself using actions and state sharing
- Creating side effects to make plugins interact in more strict ways should not be done at the plugin level, orchestrating different plugins should be delegated at the top (application) level
- Use containers configuration to combine plugins in containers

# Writing Epics

Most of the asynchronous operations we are doing in MapStore2 are implemented using epics. This guide gives the developer the base concepts about epics and provides the best practices to write and add your epics to a MapStore2 project.

## Base Concepts

**Epics** are the core element of the redux middleware called redux-observable. **redux-observable** is based on **RxJS**.

**RxJS** is a library for reactive programming using **Observables**, to make it easier to compose asynchronous or callback-based code.

stream The concept of stream is "sequence of data made available over time.".

--a---b-c---X---|->
a, b, c, d are emitted values
X is an error
| is the 'completed' signal
---> is the timeline

**Observable** is the core entity of RxJS and, more generically, of the whole reactive programming paradigm. Basically it is an entity that emits events and can be subscribed to, so that subscribers can intercept the events emitted. This is the entity that implements the concept of **stream** (so *stream* and *Observable* are almost used as synonym).

Subscribing to observables can be hard, so RxJs provides a lot of **operators** to help manipulating and combining observables (so, *streams*). Here an example of how operators allow manipulating an event stream to count clicks:

The final stream can be finally subscribed to update, for instance, a counter on the UI.

### Versions

At the time of writing this documentation MapStore2 is using RxJS 5.1.1 and redux-observable 0.19.0. So make you sure to check the correct documentation about the current versions of these libraries.

### What is an epic

An **epic** is basically nothing more than:

a function that returns a stream of redux actions to emit.

A simple epic in mapstore can be this one:

```
const fetchUserEpic = (action$, store) => action$
    .ofType(MAP_CONFIG_LOADED)
    .filter(() =>
isMapLoadConfigurationEnabled(store.getState()))
    .map({
        type: NOTIFICATION,
        message: "Map Loaded"
    });
);
```

The epic function has 2 arguments:

- action\$ : the stream of redux actions. Every time an action is triggered through redux, it is emitted as an event on the action\$ stream.
- store. A small version of the redux store, that contains essentially only one important method called getState(). This method returns the current redux state object.

This function **must return** a new stream that emits the actions we want to dispatch to redux. The **redux-observable** middleware subscribes to the action streams returned by the epics so the actions will be automatically triggered on redux.

**NOTE**: **redux-observable** middleware is already added to the MapStore2's StandardStore and StandardApp, so a developer should only take care of creating his own epics and add them to MapStore.

Typically the stream returned by an epic is always listening for new actions and dispatches other actions:

actions in, actions out.

Let's analyze the epic reported as first example:

It returns a stream ( arrow function ( => ) implicit return) manipulating the action\$ stream. It first filters out all the unwanted actions catching only the MAP\_CONFIG\_LOADED action types, then another filter checks the state to verify some condition (typically a selector can be used to check the state).

**NOTE**: **redux-observable** adds an operator to rxjs called **ofType** that simply filters the actions of certain types, passed as argument, but it is not a part of standard RxJS operators.

The events that passed the 2 filters then hit the map operator. The map operator simply returns the (action) object:

```
{
   type: NOTIFICATION,
```

```
message: "Map Loaded"
}
```

This object will be emitted on the returning stream and so the action will be triggered in redux.

Of course instead of emitting the plain object, you can use an action creator, like this:

```
const notifyMapLoaded = (action$, store) => action$
    .ofType(MAP_CONFIG_LOADED)
    .filter(() =>
isMapLoadConfigurationEnabled(store.getState()))
    .map(info({
        message: "Map Loaded"
    }))
);
```

# Create complex data flows triggered by actions

Typical operators to start creating a complex data flow are:

- switchMap
- mergeMap
- exhaustMap, forkJoin and many others...

The base concept of all these solutions is to create one or more new streams (using a function passed as argument) and then emit the events on the final Observer.

Note: Creating Higher order observables (that are basically streams of streams) and merging their events is a common pattern in RxJs, so, mergeMap and switchMap are simpler shortcuts to increase readability and maintainability of the code:

- mergeMap() is just map() + mergeAll()
- switchMap() is just map() + switch().

#### Example:

```
---{seconds: 5}-----> action in
vv switchMap vvvvvvvvvvvvvvvvvvvvvvvvvv
-----{5}--{4}--{3}--{2}--{1}--> action out
```

In this epic, every time START\_COUNTDOWN action is performed, the switchMap operator's argument function will be executed. The argument function of switchMap must return an Observable. Every value emitted on this stream will be projected on the main flow.

So on the first START\_COUNTDOWN the timer starts

(Rx.Observable.interval(1000)). The timer will emit an incremental value (0, 1, 2, ...) every 1000 milliseconds. This value is used to trigger another action to emit on redux (using an action creator called updateTime, for instance).

At the end the stream will be closed after the n seconds because of the takeUntil: .takeUntil(Rx.Observable.timer(seconds \* 1000)) unsubscribes the observable when the stream passed as function emits a value.

switchMap operator unsubscribes its observable ( so stops getting events from it ) even if another event comes on the main stream (so in this case another START\_COUNTDOWN action).

If you don't want to stop listening you may need to use mergeMap instead.

Imagine to have to modify the epic above to manage many countdowns, identified by an id. In this case a START\_COUNTDOWN event should not stop the ones already started. You can do it using mergeMap.

In this case the streams will look like this:

## Doing AJAX

Ajax calls in MapStore should all pass by libs/ajax.js. This is an axios instance that adds the support for using proxies or CORS.

Axios is a library that uses ES6 Promises to do ajax calls. Luckily RxJs allows to use Promises instead of streams in most of the cases. In the other cases, there is a specific operator called defer that you can use to wrap your Promise into a stream.

NOTE: It is perfectly normal to consider the concept of Promise as a special case of a stream, that emit only one value, then closes.

So, every time you have to do an ajax call, you will need to use axios:

Example with defer :

## Epic state: muted / unmuted

All the epics attached to plugins or extension will be registered once plugin is loaded.

Each registered epic can be in one of two possible states:

**muted**: no reaction to the actions that comes in **unmuted**: reacting to the listed actions

- Whenever new epic is registered it will be in unmuted state by default.
- Epic will become muted whenever there is no plugin/extension on the page listing that specific epic in plugin definition. In other words, if there are Extension1 and Plugin2, both are adding epic called testEpic and both plugin and extension are not added to the current page plugins in pluginsConfig, then epic will become muted.

## Muted epics: how to mute internal streams

MapStore will mute all the epics whenever corresponding plugin or extension is not rendered on the page. Though, it might be the case that one of your epics will return internal stream, like in example below:

```
export const dummyEpic = (action$, store) =>
action$.ofType(ACTION)
   .switchMap(() => {
      return Rx.Observable.interval(1000)
      .switchMap(() => {
           console.log('TEST');
           return Rx.Observable.empty();
        });
});
```

In this case, internal stream should be muted explicitly.

Each epic receives third argument type of object, having property called pluginRenderStream\$. Combined with semaphore it allows to mute internal stream whenever epic is muted:

```
export const dummyEpic = (action$, store, {
    pluginRenderStream$ }) => action$.ofType(ACTION)
    .switchMap(() => {
        return Rx.Observable.interval(1000)
        .let(semaphore(pluginRenderStream$.startWith(true)))
        .switchMap(() => {
            console.log('TEST');
            return Rx.Observable.empty();
        });
    });
```

# Writing Actions and Reducers

## What are actions?

### Quoting the redux documentation they are:

Actions are payloads of information that send data from your application to your store.

They are simply plain JavaScript objects

```
/* trigger the panning action of the map to a center point */
const center = [42.3, 36.5];
export const PAN_TO = 'MAP:PAN_TO';
{
    type: PAN_TO,
    center
}
```

They must have type property, typically a constant with a string value, but any other properties are optional

## Why we use them

We need them to trigger changes to the application's store via reducers. To do that we use Action Creators

## Action Creators

They are simply function that returns actions objects

```
const defaultValue = [42.3, 36.5];
/*
 * by convention, use an initial name (the action filename)
 * in order to describe better the action type, in this case MAP
 * separated by a colon : and the action constant name
 */
export const PAN_TO = 'MAP:PAN_TO';
export const panTo = (center = defaultValue) => ({
   type: PAN_TO,
      center
});
```

**Note:** Stick to es6 import/export module system and when possible provide a default value for the parameters

These action creators are used in the connected components or in MapStore2 plugins But actions by themselves are not enough we need Reducers that intercepts those actions and change the state accordingly.

**Note:** Remember to put all the actions .js files in the web/client/actions folder or in js/actions if you are working with custom plugins

## Reducers

#### Again quoting redux documentation they are:

Reducers specify how the application's state changes in response to actions sent to the store.

Reducers are pure functions that take the previous state and an action and return a new state

(previousState, action) => newState

let's see an example:

```
// @mapstore is an alias for dir_name/web/client (see
webpack.config.js)
import {PAN_TO} from '@mapstore/actions/map';
export default function map(state, action) {
    switch (action.type) {
        case PAN_TO: {
            return {
                ...state,
                center: action.center
            };
        }
        default: return state;
    }
}
```

As you can see we are changing the center of the map that triggers the panning action of the mapping library

And that's it we have wrote an action and a reducers that make the map panning around.

**Note:** Remember to put all the reducers .js files in the web/client/reducers folder or in js/reducers if you are working with custom plugins

### Advanced usage and tips

Sometimes you need to change a value of an item which is stored inside an array or in a nested object.

Let's imagine we have this object in the store:

```
layer: {
   features: [object_1, object_2, ...object_n]
}
```

And we have created an action that holds the id of the object to change and some properties

```
export const UPDATE_LAYER_FEATURE = 'LAYER:UPDATE_LAYER_FEATURE'
export const updateFeature = (id, props = {}) => ({type:
UPDATE_LAYER_FEATURE, id, props})
```

Then in the reducer we can have different implementations. Here we show the one using **arrayUpdate** from @mapstore/utils/ImmutableUtils for updating objects in array

```
import {UPDATE_LAYER_FEATURE} from '@mapstore/actions/layer';
import {find} from 'lodash';
const defaultState = {
    features: [{ id: 1, type: "Feature", geometry: { type :
"Point", coordinates: [1, 2]}}]
};
export default function layer(state = defaultState, action) {
    switch (action.type) {
       case UPDATE_LAYER_FEATURE: {
            // let's assume that action.props = {newProp:
"newValue" }
           const feature = find(state.features, {id:
action.id});
            // merging the old feature object with the new prop
while replacing the existing element in the array
            const newFeature = {...feature, ...action.props};
            return arrayUpdate("features", newFeature, {id:
action.id}, state);
            // after this you expect to find the new properties
in the feature specified by the id
       }
       default: return state;
   }
}
```

### Testing

Tests in mapstore are stored in <u>\_\_tests\_\_</u> folder at the same level where actions/reducer are. The file name is the same of the action/reducer with a '-test' suffix

```
actions/map.js
actions/__tests__/map-test.js
or
reducers/map.js
reducers/__tests__/map-test.js
```

We use expect as testing library, therefore we suggest to have a look there.

### How to test an action

Typically you want to test the type and the params return from the action creator

let's test the mapTo action:

```
// copyright section
import expect from 'expect';
import {panTo, PAN_TO} from '@mapstore/actions/map';
describe('Test correctness of the map actions', () => {
    it('testing panTo', () => {
        const center = [2, 3];
        const center = [2, 3];
        const returnValue = panTo(center);
        expect(returnValue.type).toEqual(PAN_TO);
        expect(returnValue.center).toEqual(center);
    });
});
```

In order to speed up the unit test runner, you can:

- change the path in tests.webpack.js (custom/standard project) or build\tests.webpack.js (framework) to point to the folder parent of tests for example '/js/actions' for custom/standard project or '../web/client/ actions' for framework
- then run this command: npm run test:watch

This allows to run only the tests contained to the specified path. **Note:** When all tests are successfully passing remember to restore it to its original value.

## How to test a reducer

Here things can become more complicated depending on your reducer but in general you want to test all cases

```
// copyright section
import expect from 'expect';
import {panTo} from '@mapstore/actions/map';
import map from '@js/reducers/map'; // the one created before
not the one present in @mapstore/reducers
describe('Test correctness of the map reducers', () => {
    it('testing PAN_TO', () => {
        const center = [2, 3];
        const center = [2, 3];
        const state = map({}, panTo(center));
        // here you have to check that state has changed
accordingly
        expect(state.center).toEqual(center);
    });
});
```

Here for speedup testing you can again modify the tests.webpack.js (custom/ standard project) or build\tests.webpack.js (framework) in order to point to the reducers folder and then running npm run test:watch

## Actions and epics

Actions are not only used by redux to update the store (through the reducers), but also for triggering side effects workflows managed by epics

For more details see Writing epics

# Configuring MapStore

MapStore (and every application developed with MapStore) allows customization through configuration. To understand how to configure MapStore you have to know that the back-end and the front-end of MapStore have two different configuration systems.

This separation allows to:

- Make mapstore configuration system live also as a front-end only framework
- · Keep the power of customization provided by spring on the back-end

## Back-end Configuration Files

They are .properties files or .xml files, and they allow to configure the various parts of the back-end. They are located in java/web/src/main/ resources and they will be copied in MapStore.war under the directory /WEB-INF/classes.

- proxy.properties : configuration for the internal proxy (for cross-origin requests). More information here.
- geostore-datasource-ovr.properties : provides settings for the database.
- log4j2.properties : configuration for back-end logging
- sample-categories.xml: initial set of categories for back-end resources
  (MAP, DASHBOARD, GEOSTORY...)
- mapstore.properties : allow specific overrides to front-end files, See externalization system for more details

Except for mapstore.properties and ldap.properties, all these files are simply overrides of original configuration files coming from the included sub-applications part of the back-end. In WEB-INF/classes you will find also some other useful files coming from the original application:

### Back-end security configuration files

Back-end security can be configured to use different authentication strategies. Maven profiles can be used to switch between these different strategies.

Depending on the chosen profile a different file will be copied from the product/ config folder to override WEB-INF/classes/geostore-spring-security.xml in the final package. In particular:

- default: db\geostore-spring-security-db.xml (geostore database)
- Idap: ldap\geostore-spring-security-ldap.xml (LDAP source)

Specific configuration files are available to configure connection details for the chosen profile.

For example, if using LDAP, look at LDAP integration.

### Log4j2 configuration file

Below will be presented some basic pointers to configure logging through the log4j2.properties file. For more informations see the official documentation page.

The following is the default MapStore log4j2.properties file.

```
rootLogger.level = INFO
appenders= console, file
appender.console.type = Console
appender.console.name = LogToConsole
appender.console.layout.type = PatternLayout
appender.console.layout.pattern = %p %d{yyyy-MM-dd
HH:mm:ss.SSS} %c::%M:%L - %m%n
rootLogger.appenderRef.stdout.ref = LogToConsole
rootLogger.appenderRef.console.ref = LogToConsole
appender.file.type = File
appender.file.name = LogToFile
appender.file.fileName=${sys:catalina.base}/logs/mapstore.log
appender.file.layout.type=PatternLayout
```

```
appender.file.layout.pattern=%p %d{yyyy-MM-dd HH:mm:ss.SSS}
%C{1}.%M() - %m %n
rootLogger.appenderRef.file.ref = LogToFile
logger.restsrv.name=it.geosolutions.geostore.services.rest
logger.restsrv.level= INF0
logger.hibernate1.name=org.hibernate
logger.hibernate1.level=INF0
logger.trg1.name=com.trg
logger.trg1.level=INF0
```

The first two properties defines the rootLogger level and appenders declarations.

rootLogger.level = INF0
appenders= console, file

The following properties configure two appenders: one that writes log messages to the console and the other to a log file. In both cases a pattern layout has been configured through a conversion pattern strings to format the log messages (more details about patterned layouts are available here). For the file appender we have configured as well the location of the log file to which writing log messages (property appender.file.fileName). Note the \$ {sys:catalina.base} variable, used as a placeholder of the root folder of the tomcat instance where MapStore is deployed.

```
appender.console.type = Console
appender.console.name = LogToConsole
appender.console.layout.type = PatternLayout
appender.console.layout.pattern = %p %d{yyyy-MM-dd
HH:mm:ss.SSS} %c::%M:%L - %m%n
rootLogger.appenderRef.stdout.ref = LogToConsole
rootLogger.appenderRef.console.ref = LogToConsole
appender.file.type = File
appender.file.name = LogToFile
appender.file.fileName=${sys:catalina.base}/logs/mapstore.log
appender.file.layout.type=PatternLayout
appender.file.layout.pattern=%p %d{yyyy-MM-dd HH:mm:ss.SSS}
%C{1}.%M() - %m %n
rootLogger.appenderRef.file.ref = LogToFile
```

In the final section of the properties file the loggers for specific package name are configured. In this case the syntax is logger.{a\_name\_of\_choice}.name to declare the package to which the configured logger belongs and logger. {a\_name\_of\_choice}.level to declare the log level of that logger.

```
logger.restsrv.name=it.geosolutions.geostore.services.rest
logger.restsrv.level= INFO
logger.hibernate1.name=org.hibernate
logger.hibernate1.level=INFO
logger.trg1.name=com.trg
logger.trg1.level=INFO
```

## Front-end Configurations Files

They are JSON files that will be loaded via HTTP from the client, keeping most of the framework working also in an html-only context (when used with different back-ends or no-backend). These JSON files are located in web/client/configs directory and they will be copied in the configs of the war file.

Several configuration files (at development and / or run time) are available to configure all the different aspects of an application.

- localConfig.json : Dedicated to the application configuration. Defines all general settings of the front-end part, with all the plugins for all the pages. See Application Configuration for more information.
- new.json Can be customized to set-up the initial new map, setting the backgrounds, initial position .. See Maps configuration for more information.
- pluginsConfig.json : Allows to configure the context editor plugins list. See Context Editor Configuration for more information.

# Externalize Configurations

Typically configuration customization should stay outside the effective application installation directory to simplify future updates. Updates in fact are usually replacement of the old application file package with the newer one. Changes applied directly inside the application package may be so removed on every update. For this reason MapStore provides a externalization system for both the configuration systems. See Externalize Configuration section to learn how to do this.

# Application configuration

The application will load by default it will load the localConfig.json which is now stored in the configs folder

You can load a custom configuration by passing the localConfig argument in query string:

```
localhost:8081/?localConfig=myConfig#/viewer/openlayers/0
```

The **localConfig** file contains the main information about URLs to load and plugins to load in the various modes.

This is the main structure:

```
{
 // URL of geoStore
  "geoStoreUrl": "rest/geostore/",
  // printURL the url of the print service, if any
  "printUrl": "/geoserver-test/pdf/info.json",
  // a string or an object for the proxy URL.
  "proxyUrl": {
    // if it is an object, the url entry holds the url to the
proxy
    "url": "/MapStore2/proxy/?url=",
    // useCORS array contains a list of services that support
CORS and so do not need a proxy
    "useCORS": ["http://nominatim.openstreetmap.org", "https://
nominatim.openstreetmap.org"]
 }.
 // JSON file where uploaded extensions are configured
  "extensionsRegistry": "extensions.json",
 // URL of the folder from where extensions bundles and other
assets are loaded
 "extensionsFolder": "",
 // API keys for bing and mapquest services
  "bingApiKey",
 // force dates to be in this specified format. use moment js
format pattern
  "forceDateFormat": "YYYY-MM-DD",
```

```
// force time to be in this specified format. use moment is
format pattern
  "forceTimeFormat": "hh:mm A",
  "mapquestApiKey",
  // list of actions types that are available to be launched
dynamically from query param (#3817)
  "initialActionsWhiteList": ["ZOOM_TO_EXTENT",
"ADD_LAYER", ...],
  // path to the translation files directory (if different from
default)
  "translationsPath",
  // if true, every ajax and mapping request will be
authenticated with the configurations if match a rule (default:
true)
  "useAuthenticationRules": true
  // the authentication rules to match
  "authenticationRules": [
  { // every rule has a `urlPattern` regex to match
    "urlPattern": ".*geostore.*",
    // and a authentication `method` to use (basic, authkey,
browserWithCredentials)
    "method": "basic"
  }, {
    "urlPattern": "\\/geoserver.*",
    "method": "authkey"
  }],
  // flag for postponing mapstore 2 load time after theme
  "loadAfterTheme": false,
  // if defined, WMS layer styles localization will be added
  "localizedLayerStyles": {
      // name of the ENV parameter variable that is needed for
localization proposes
      "name": "mapstore_language"
  },
  // flag for abandon map edit confirm popup, by default is
enabled
  "unsavedMapChangesDialog": false,
  // optional flag to set default coordinate format (decimal,
aeronautical)
  "defaultCoordinateFormat": "aeronautical",
  // optionals misc settings
  "miscSettings": {
      // Use POST requests for each WMS length URL highter than
this value.
     "maxURLLength": 5000
  },
  // optional state initializer (it will override the one
defined in appConfig.js)
  "initialState": {
```

```
// default initial state for every mode (will override
initialState imposed by plugins reducers)
      "defaultState": {
          . . .
          // if you want to customize the supported locales put
here the languages you want and follow instruction linked below
          "locales": {
            "supportedLocales": {
              "it": {
                "code": "it-IT",
                "description": "Italiano"
              },
              "en": {
                "code": "en-US",
                "description": "English"
              }
          }
        }
      },
      // mobile override (defined properties will override
default in mobile mode)
      "mobile": {
          . . .
      }
  },
  // allows to apply map options configuration to all the Map
plugins instances defined in the plugins configuration.
  // The mapOptions in the plugin configuration have priority
so they will overrides this global config
  "defaultMapOptions": {
    "openlayers": { ... },
    "leaflet": { ... },
    "cesium": { ... }
  },
  "plugins": {
      // plugins to load for the mobile mode
      "mobile": [...]
      // plugins to load for the desktop mode
      "desktop": [...]
      // plugins to load for the embedded mode
      "embedded": [...]
      // plugins to load for the myMode mode
      "myMode": [...]
 }
}
```

If you are building your own app, you can choose to create your custom modes or force one of them by passing the mode parameter in the query string.

For adding a new locale or configuring currently supported locales, go check this out.

For configuring plugins, see the Configuring Plugins Section and the plugin reference page

## Explanation of some config properties

- **loadAfterTheme** is a flag that allows to load mapstore.js after the theme which can be versioned or not(default.css). default is false
- **initialState** is an object that will initialize the state with some default values and this WILL OVERRIDE the initialState imposed by plugins & reducers.
- **projectionDefs** is an array of objects that contain definitions for Coordinate Reference Systems

### initialState configuration

It can contain:

- 1. a defaultState valid for every mode
- 2. a piece of state for each mode (mobile, desktop, embedded)

#### **Catalog Tool configuration**

Inside defaultState you can set default catalog services adding the following key

```
"catalog": {
    "default": {
        "newService": {
            "url": "",
            "type": "wms",
            "title": "",
            "isNew": true,
            "editable": true,
            "autoload": false
```

```
},
    "selectedService": "Demo CSW Service",
    "services": {
      "Demo CSW Service": {
        "url": "https://demo.geo-solutions.it/geoserver/csw",
        "type": "csw",
        "title": "A title for Demo CSW Service",
       "autoload": true
      },
      "Demo WMS Service": {
        "url": "https://demo.geo-solutions.it/geoserver/wms",
        "layerOptions": {
          "tileSize": 512
          },
          "format": "image/png8"
        "type": "wms",
        "title": "A title for Demo WMS Service",
        "autoload": false
      },
      "Demo WMTS Service": {
        "url": "https://demo.geo-solutions.it/geoserver/gwc/
service/wmts",
        "type": "wmts",
        "title": "A title for Demo WMTS Service",
        "autoload": false
     }
   }
 }
}
```

Set selectedService value to one of the ID of the services object ("Demo CSW Service" for example).

This will become the default service opened and used in the catalog panel. For each service set the key of the service as the ID.

```
"ID_CATALOG_SERVICE": {
    "url": "the url pointing to the catalog web service",
    "type": "the type of webservice used. (this need to be
    consistent with the web service pointed by the url)",
    "title": "the label used for recognizing the catalog service",
    "autoload": "if true, when selected or when catalog panel is
    opened it will trigger an automatic search of the layers. if
    false, search must be manually performed."
        "readOnly": "if true, makes the service not editable from
    catalog plugin"
```

```
"titleMsgId": "optional, string used to localize the title of
the service, the string must be present in translations",
 "format": "image/png8" // the image format to use by default
for layers coming from this catalog (or tiles).
  "layerOptions": { // optional
      "format": "image/png8", // image format needs to be
configured also inside layerOptions
     "serverType": "geoserver or no-vendor, depending on this
some geoserver vendor extensions will be used for WMS
requests.",
      "tileSize": 512 // determine the default tile size for
the catalog, valid for WMS and CSW catalogs
 },
 "filter": { // applicable only for CSW service
      "staticFilter": "filter is always applied, even when
search text is NOT PRESENT",
      "dynamicFilter": "filter is used when search text is
PRESENT and is applied in `AND` with staticFilter. The template
is used with ${searchText} placeholder to append search string"
 }
}
```

#### CSW service

filter - For both static and dynamic filter, input only xml element contained within (i.e. Do not enclose the filter value in )

Example:

```
{
    "filter": { // Default filter values
        "staticFilter":
    "<ogc:Or><ogc:PropertyIsEqualTo><ogc:PropertyName>dc:type</
    ogc:PropertyName><ogc:Literal>dataset</ogc:Literal></
    ogc:PropertyIsEqualTo><ogc:PropertyIsEqualTo><ogc:PropertyName>dc:
    ogc:PropertyName><ogc:Literal>http://purl.org/dc/dcmitype/
Dataset</ogc:Literal><//ogc:PropertyIsEqualTo></ogc:Or>",
        "dynamicFilter": "<ogc:PropertyIsLike wildCard='%'
    singleChar='_' escapeChar='\\'><ogc:PropertyName>csw:AnyText</
    ogc:PropertyIsLike>"
    }
}
```

Be careful to use unique IDs

Future implementations will try to detect the type from the url.

newService is used internally as the starting object for an empty service.

#### Annotations Editor configuration

Annotations editor can be configured by setting it's defaultState. It looks like this:

```
"defaultState": {
 . . .
  "annotations": {
    "config": {
    "geometryEditorOptions": {
        "measureOptions": {
          "displayUom": "nm"
        }
      },
      "multiGeometry": true,
      "validationErrors": {},
      "defaultPointType": "symbol"
    },
    "format": "aeronautical",
    "defaultTextAnnotation": "New"
  },
```

- · format decimal or aeronautical degree for coordinates
- · defaultTextAnnotation default text value for text annotations
- config.geometryEditorOptions properties to be passed to CoordinatesEditor of GeometryEditor. For more information refer to the documentation of CoordinatesEditor component
- **config.multiGeometry** if set to true allows to add more then one geometry to annotations
- **config.defaultPointType** default point type of marker geometry type. Can be 'marker' or 'symbol'

### projectionDefs configuration

Custom CRS can be configured here, at root level of localConfig.json file. For example:

```
"projectionDefs": [{
    "code": "EPSG:3003",
    "def": "+proj=tmerc +lat_0=0 +lon_0=9 +k=0.9996 +x_0=1500000
+y_0=0
+ellps=intl+towgs84=-104.1,-49.1,-9.9,0.971,-2.917,0.714,-11.68
+units=m +no_defs",
    "extent": [1241482.0019, 973563.1609, 1830078.9331,
5215189.0853],
    "worldExtent": [6.6500, 8.8000, 12.0000, 47.0500]
}]
```

Explanation of these properties:

- · code a code string that will identify the added projection
- · def projection definition in PROJ.4 format
- extent projected bounds of the projection
- worldExtent bounds of the projection in WGS84

These parameters for a projection of interest can be found on epsg.io

**CRS Selector configuration** 

CRS Selector is a plugin, that is configured in the plugins section. It should look like this:

```
"plugins": {
    ...
    "desktop": [
        ...}, {
        "name": "CRSSelector",
        "cfg": {
            "additionalCRS": {
               "EPSG:3003": {
                    label: "Monte Mario"
```

Configuration parameters are to be placed in the "cfg" object. These parameters are:

- additionalCRS object, that contains additional Coordinate Reference Systems. This configuration parameter lets you specify which projections, defined in projectionDefs, should be displayed in the CRS Selector, alongside default projections. Every additional CRS is a property of additionalCRS object. The name of that property is a code of a corresponding projection definition in projectionDefs. The value of that property is an object with the following properties:
- **label** a string, that will be displayed in the CRS Selector as a name of the projection
- **filterAllowedCRS** which default projections are to be available in the selector. Default projections are:
- EPSG:3857
- EPSG:4326
- allowedRoles CRS Selector will be accessible only to these roles. By default, CRS Selector will be available for any logged in user.

### Search plugin configuration

The search plugin provides several configurations to customize the services behind the search bar in the map:

- Allow to configure more many services to use in parallel, in the services array.
- Natively supports nominatim and WFS protcols
- Allows to register your own custom services to develop and use in your custom project
- Allows to configure services in cascade, typically when you have a hierarchical data structures (e.g. search for municipality, then for street name, than for house number, or search state, then region, then specific feature, and so on...)

Following you can find some examples of the various configurations. For more details about the properties, please check to plugin API documentation: https://mapstore.geosolutionsgroup.com/mapstore/docs/api/plugins#plugins.Search

Nominatim configuration:

```
{
    "type": "nominatim",
    "searchTextTemplate": "${properties.display_name}", // text
to use as searchText when an item is selected. Gets the result
properties.
    "options": {
        "polygon_geojson": 1,
        "limit": 3
}
```

WFS configuration:

```
"plugins": {
...
"desktop": [
...}, {
"name": "Search",
```

```
"cfg": {
        "showCoordinatesSearchOption": false,
        "maxResults": 20,
        "searchOptions": {
          "services": [{
            "type": "wfs",
            "priority": 3,
            "displayName": "${properties.propToDisplay}",
            "subTitle": " (a subtitle for the results coming
from this service [ can contain expressions like $
{properties.propForSubtitle}])",
            "options": {
              "url": "/geoserver/wfs",
              "typeName": "workspace:layer",
              "queriableAttributes": ["attribute_to_query"],
              "sortBy": "id",
              "srsName": "EPSG:4326",
              "maxFeatures": 20,
              "blacklist": ["... an array of strings to exclude
from the final search filter "]
            }
        1
        }
      }
    }, {
 1
}
```

WFS configuration with nested services:

```
"plugins": {
    ...
    "desktop": [
    ...}, {
        "name": "Search",
        "cfg": {
            "showCoordinatesSearchOption": false,
            "maxResults": 20,
            "searchOptions": {
               "searchOptions": {
               "searchOptions": {
               "services": [{
               "type": "wfs",
               "priority": 3,
               "displayName": "${properties.propToDisplay}",
               "subTitle": " (a subtitle for the results coming
from this service [ can contain expressions like $
{properties.propForSubtitle}])",
```

```
"options": {
              "url": "/geoserver/wfs".
              "typeName": "workspace:layer",
              "queriableAttributes": ["attribute_to_query"],
              "sortBy": "id",
              "srsName": "EPSG:4326",
              "maxFeatures": 20,
              "blacklist": ["... an array of strings to exclude
from the final search filter "]
            }.
            "nestedPlaceholder": "the placeholder will be
displayed in the input text, after you have performed the first
search",
            "then": [{
              "type": "wfs",
              "priority": 1,
              "displayName": "${properties.propToDisplay} $
{properties.propToDisplay}",
              "subTitle": " (a subtitle for the results coming
from this service [ can contain expressions like $
{properties.propForSubtitle}])",
              "searchTextTemplate": "$
{properties.propToDisplay}",
              "options": {
                "staticFilter": " AND SOMEPROP = '$
{properties.OLDPROP}'", // will be appended to the original
filter, it gets the properties of the current selected item (of
the parent service)
                "url": "/geoserver/wfs",
                "typeName": "workspace:layer",
                "queriableAttributes": ["attribute_to_query"],
                "srsName": "EPSG:4326".
                  "maxFeatures": 10
                }
            }]
  }
        1
        }
      }
   }, {
  1
}
```

Custom services configuration:

```
{
 "type": "custom Service Name",
  "searchTextTemplate": "${properties.propToDisplay}",
  "displayName": "${properties.propToDisplay}",
  "subTitle": " (a subtitle for the results coming from this
service [ can contain expressions like $
{properties.propForSubtitle}])",
  "options": {
    "pathname": "/path/to/service",
    "idVia": "${properties.code}"
  },
  "priority": 2,
  "geomService" : {
    "type": "wfs",
    "options": {
      "url": "/geoserver/wfs",
      "typeName": "workspace:layer",
      "srsName": "EPSG:4326",
      "staticFilter": "ID = ${properties.code}"
   }
 }
}
```

# Configuring plugins

To configure the plugins used by your application, a dedicated section is available in the **localConfig.json** configuration file:

```
"plugins": {
    ...
}
```

Inside the **plugins** section, several modes can be configured (e.g. desktop or mobile), each one with its own list of plugins:

```
"plugins": {
    "mobile": [...],
    "desktop": [...]
}
```

Each plugin can be simply listed (and the default configuration is used):

```
"plugins": {
    ...
    "desktop": ["Map", "MousePosition", "Toolbar", "TOC"]
}
```

or fully configured:

```
"plugins": {
    ...
    "desktop": [{
        "name": "Map",
        ...
        }
    },
    ...
    ]
}
```

## Dynamic configuration

Configuration properties of plugins can use expressions, so that they are dynamically bound to the application state.

An expression is anything between curly brackets ({...}) that is a javascript expression, where the **monitored state** of the application is available as a set of variables.

To define the monitored state, you have to add a **monitorState** property in **localConfig.json**.

```
{
    ...
    "monitorState": [{"name": "mapType", "path":
    "mapType.mapType"}]
    ...
}
```

Where:

- name is the name of the variable that can be used in expressions
- **path** is a javascript object path to the state fragment to be monitored (e.g. map.present.zoom)

When you have a monitored state, you can use it in configuration properties this way: Be sure to write a valid javascript expression.

```
"cfg": {
    ...
    "myProp": "{state('mapType') === 'openlayers' ? 1 : 2}"
    ...
}
```

Expressions are supported in **cfg** properties and in **hideFrom** and **showIn** sections.

In addition to monitored state also the **page request parameters** are available as variables to be used in expressions.

```
Look at the plugin reference page for a list of available configuration properties.
```

# Map Configuration

By default MapStore is able to open maps with this path in the URL:

http://localhost:8081/#viewer/<maptype>/<mapId>

Where:

- maptype can be leaflet openlayers or cesium.
- mapId can be a number or a string.
- A **number** represents standard maps, stored on the database.
- A string instead represents a static json file in the root of the application.

The first case can be used to load a map from the maps database, using its id.

There is a special mapId, 0 (zero), that is used to load a basic OSM map for demo purposes.

http://localhost:8081/#viewer/openlayers/0

The configuration of this map is stored in the static config.json file in the root of the project.

The second case can be used to define standard map contexts.

This is used for the **new map**. If you're logged in and allowed to create maps, when you try to create a new map you will see the the application will bring you to the URL:

#### http://localhost:8081/#viewer/openlayers/new

This page uses the new.json file as a template configuration to start creating a new map. You can find this file in web/client/configs directory for standard

MapStore or in configs/ folder for a custom projects. You can edit new.json to customize this initial template. It typically contains the map backgrounds you want to use for all the new maps (identified by the special property "group": "background").

If you have enabled the datadir, then you can externalize the new.json or config.json files. (see here for more details)

new.json and config.json are special cases, but you can configure your own static map context creating these json files in the root of the project, for instance mycontext.json and accessing them at the URL:

```
http://localhost:8081/#viewer/openlayers/mycontext
```

**important note**: new.json and config.json are special files and don't require the version. For other map context, you **must** specify the version of the map file type in the root of the json file:

```
{
    "version": 2,
    // ...
}
```

These static map contexts are accessible by anyone. If you want to customize standard maps (that are listed in home page and where you can define) manually, you will have to edit the maps using the GeoStore REST API.

## Map options

The following options define the map options (projection, position, layers):

- projection: {string} expressed in EPSG values
- units: {string} uom of the coordinates
- center: [object] center of the map with starting point in the bottom-left corner

- zoom: {number} level of zoom
- resolutions: {number[]} resolutions for each level of zoom
- scales: {number[]} scales used to compute the map resolutions
- maxExtent: {number[]} max bbox of the map expressed [minx, miny, maxx, maxy]
- layers: {object[]} list of layers to be loaded on the map
- groups {object[]}: contains information about the layer groups

i.e.

```
{
    "version": 2,
    "projection": "EPSG:900913",
    "units": "m",
    "center": {"x": 1000000.000000, "y": 5528000.000000, "crs":
"EPSG:900913"}.
    "zoom": 15,
    "mapOptions": {
      "view": {
        "scales": [175000, 125000, 100000, 75000, 50000, 25000,
10000, 5000, 2500],
        "resolutions": [
          84666.666666688,
          42333.3333333344,
          21166.6666666672,
          10583.33333333336.
          5291.6666666668,
          2645.83333333334,
          1322.91666666667,
          661.458333333335000,
          529.16666666668000,
          396.875000000001000,
          264.58333333334000,
          132.291666666667000,
          66.145833333333500.
          39.68750000000100,
          26.45833333333400
          13.2291666666666700,
          6.614583333333350,
          3.96875000000010,
          2.645833333333340,
          1.322916666666670,
          0.6614583333333335
```

#### Note

The option to configure a list of scale denominators allow to have them in human friendly format, and calculate the map resolutions from scales.

#### Warning

If the scales and resolutions property are declared, in the same json object, the scales have priority. In the array, the values have be in descending order.

#### Warning

Actually the custom resolution values are valid for one single CRS. It's therefore suggested to avoid to add this parameter when multiple CRSs in the same map configuration are needed.

## Layers options

Every layer has it's own properties. Anyway there are some options valid for every layer:

- title: {object|string} the title of the layer, can be an object to support i18n.
- type: {string} the type of the layer. Can be wms, wmts, osm ...
- name: {string} the name is used as general reference to the layer, or as title, if the title is not specified. Anyway, it's usage depends on the specific layer type.

- group: {string}: the group of the layer (in the TOC). Nested groups can be indicated using /.i.e. Group/SubGroup. A special group, background, is used to identify background layers. These layers will not be available in the TOC, but only in the background switcher, and only one layer of this group can be visible.
- thumbURL: {string}: the URL of the thumbnail for the layer, used in the background switcher ( if the layer is a background layer )
- visibility: {boolean}: indicates if the layer is visible or not
- queriable: {boolean}: Indicates if the layer is queriable (e.g. getFeatureInfo). If not present the default is true for every layer that have some implementation available (WMS, WMTS). Usually used to set it explicitly to false, where the query service is not available.
- hideLoading : {boolean}. If true, loading events will be ignored ( useful to hide loading with some layers that have problems or trigger errors loading some tiles or if they do not have any kind of loading.).
- minResolution : {number} : layer is visible if zoom resolution is greater or equal than this value (inclusive)
- maxResolution: {number}: layer is visible if zoom resolution is less than this value (exclusive)
- disableResolutionLimits : {boolean} : this property disables the effect of minResolution and maxResolution if set to true

i.e.

```
{
    "title": "Open Street Map",
    "name": "mapnik",
    "group": "background",
    "visibility": false,
    "hidden": true
}
```

**Localized titles**: In these configuration files you can localize titles using an object instead of a string in the title entry. In this case the title object has this shape:

```
title: {
    'default': 'Meteorite Landings from NASA Open Data
Portal', // default title, used in case the localized entry is
not present
    'it-IT': 'Atterraggi meteoriti', // one string for each
IETF language tag you want to support.
    'en-US': 'Meteorite Landings',
    'fr-FR': 'Débarquements de météorites'
    },
```

The layers can belong to the background group, in this case they will be available in the background switcher, and only one layer of this group can be visible at the same time.

```
{
    "format": "image/jpeg",
    "name": "workspace:layername",
    "params": {},
    "singleTile": false,
    "title": "My WMS Background",
    "type": "wms",
    "group": "background",
    "thumbURL": "http://some.wms.service/geoserver/ows?
SERVICE=WMS&REQUEST=GetMap&VERSION=1.3.0&LAYERS=rv%3Arv1&STYLES=&F
    "url": "http://some.wms.service/geoserver/ows",
    "visibility": false
    },
```

In the case of the background the thumbURL is used to show a preview of the layer in the background switcher.

### Layer types

- wms : WMS Web Mapping Service layers
- osm : OpenStreetMap layers format
- tileprovider : Some other mixed specific tile providers
- wmts : WMTS: Web Map Tile Service layers
- bing : Bing Maps layers

- google : Google Maps layers
- mapquest : MapQuest layers
- graticule : Vector layer that shows a coordinates grid over the map, with optional labels
- empty : special type for empty background
- 3dtiles: 3d tiles layers
- terrain : layers that define the elevation profile of the terrain

#### WMS

i.e.

```
{
    "type": "wms",
    "url": "http..." // URL of the WMS Service
    "name": "TEST:TEST", // The name of the layer
    "format": "image/png8" // format
    "title": "Open Street Map",
    "name": "mapnik",
    "group": "background",
    "visibility": false,
    "params": {}, // can be used to add parameters to the
request, or override the default ones
    "layerFilter": {} // a layer filter object, to filter the
layer
    "search": {}, // object to configure the features URL in
the layer
    "credits": { // optional
        "imageUrl": "somePic.png", // URL for the image to put
in attribution
        "link": "http://someURL.org", // URL where attribution
have to link to
        "title": "text to render" // title to show (as image
title or as text)
   }
}
```

#### Details:

• url : the URL of the WMS service

- name : name of the layer
- format : the format of the WMS requests to use
- params : an object with additional parameters to add to the WMS request
- layerFilter : an object to filter the layer. See LayerFilter for details.
- search: an object to configure the search features service. It is used to link a WFS service, typically with this shape: {url: 'http:// some.wfs.service', type: 'wfs'}.
- credits: includes the information to show in attribution.(imageUrl, link, title).

**MULTIPLE URLS** 

This feature is not yet fully supported by all the plugins, but OpenLayers supports it so if you put an array of urls instead of a single string in the layer url. Some other feature will break, for example the layer properties will stop working, so it is safe to use only on background layers.

```
{
  "type": "wms",
  "url": [
    "https://a.maps.geosolutionsgroup.com/geoserver/wms",
    "https://b.maps.geosolutionsgroup.com/geoserver/wms",
    "https://c.maps.geosolutionsgroup.com/geoserver/wms",
    "https://d.maps.geosolutionsgroup.com/geoserver/wms",
    "https://e.maps.geosolutionsgroup.com/geoserver/wms",
    "https://f.maps.geosolutionsgroup.com/geoserver/wms"
  ],
  "visibility": true,
  "opacity": 1,
  "title": "OSM",
  "name": "osm:osm",
  "group": "Meteo",
  "format": "image/png8",
  "bbox": {
    "bounds": {"minx": -180, "miny": -90, "maxx": 180, "maxy":
90},
    "crs": "EPSG:4326"
  }
},
```

#### SPECIAL CASE - THE ELEVATION LAYER

This type of layer configuration is still needed to show the elevation data inside the MousePosition plugin. The terrain layer section shows a more versatile way of handling elevation but it will work only as visualization in the 3D map viewer.

WMS layers can be configured to be used as a source for elevation related functions.

This requires:

- a GeoServer WMS service with the DDS/BIL plugin
- A WMS layer configured with **BIL 16 bit** output in **big endian mode** and **-9999 nodata value**
- a static layer in the Map plugin configuration (use the additionalLayers configuration option):
- in localConfig.json

```
{
    "name": "Map",
    "cfg": {
        "additionalLayers": [{
            "url": "http...",
            "format": "application/bil16",
            "type": "wms",
            ...
        "name": "elevation",
            "littleendian": false,
            "visibility": true,
            "useForElevation": true
        }]
    }
}
```

The layer will be used for:

- showing elevation in the MousePosition plugin (requires showElevation: true in the plugin configuration)
- as a TerrainProvider if the maptype is Cesium

in localConfig.json

```
{
    "name": "MousePosition",
    "cfg": {
        "showElevation": true,
        ...
    }
}
```

#### WMTS

The WMTS Layer configuration has a availableTileMatrixSets object that lists all the available tile matrix sets for the specific layer. Every entry of availableTileMatrixSets, identified by the ID of the tile matrix set, contains the crs and one of tileMatrixSet or tileMatrixSetLink. The first contains the definition of the tile matrix set, while the second contain the path to the tile matrix set definition in the JSON of the map configuration. This object can also optionally contain a limits entry, containing the specific limits of the layer inside the tile matrix set.

```
{
    "type": "wmts",
    "availableTileMatrixSets": {
        "google3857": {
            "crs": "EPSG:3857",
            "tileMatrixSetLink": "sources['https://
sampleServer.org/wmts/1.0.0/
WMTSCapabilities.xml'].tileMatrixSet['EPSG:3857']"
        }
    }
}
```

The sources entry of the map configuration usually contains the tile matrix sets definitions of the layers of the map, stored by their capabilitiesURL (if capabilitiesURL is not present it will use the url of the layer, in case of multiple URLs, the first one.).

A WMTS layer has also a requestEncoding entry that can be valued with RESTful or KVP. In case of RESTful the URL is a template where to place the request parameters ( see the example below ), while in the KVP case the request parameters will be passed in the query string. See the WMTS standard for more details.

e.g. (RESTful):

```
{
  "version": 2,
  // ...
  "map": {
    // ...
    "layers": [
       // WMTS layer sample
        {
        "id": "bmapoberflaeche__11",
        "name": "layer_name",
        // ...
        "type": "wmts",
        "url": [ // MULTIPLE URLS are allowed
            "https://maps1.sampleServer/{Style}/{TileMatrixSet}/
{TileMatrix}/{TileRow}/{TileCol}.jpeg",
            "https://maps2.sampleServer/{Style}/{TileMatrixSet}/
{TileMatrix}/{TileRow}/{TileCol}.jpeg",
            "https://maps3.sampleServer/{Style}/{TileMatrixSet}/
{TileMatrix}/{TileRow}/{TileCol}.jpeg",
            "https://maps4.sampleServer/{Style}/{TileMatrixSet}/
{TileMatrix}/{TileRow}/{TileCol}.jpeg",
            "https://maps.sampleServer/{Style}/{TileMatrixSet}/
{TileMatrix}/{TileRow}/{TileCol}.jpeg"
        ],
        "allowedSRS": {
          "EPSG:3857": true
        },
        "availableTileMatrixSets": {
          "google3857": {
            "crs": "EPSG:3857",
            "tileMatrixSetLink": "sources['https://
```

```
sampleServer.org/wmts/1.0.0/
WMTSCapabilities.xml'].tileMatrixSet['EPSG:3857']"
          }
        },
        // KVP (By default) or RESTful
        "requestEncoding": "RESTful",
        // identifier for the source
        "capabilitiesURL": "https://sampleServer.org/wmts/1.0.0/
WMTSCapabilities.xml",
      }
    1,
    "sources": {
      // source of the layer above
      "https://sampleServer.org/wmts/1.0.0/

                  "MatrixWidth": "4"
                  "MatrixHeight": "4"
                }
              1
```

}

#### Bing

TODO

#### Google

Note

The use of Google maps tiles in MapStore is not enabled and maintained due to licensing reasons. If your usage conditions respect the google license, you can enable the google layers by:

- Adding <script src="https://maps.google.com/maps/api/js?v=3"></script> to all html files you need it.
- Add your API-KEY to the request
- Fix the code, if needed.

example:

```
{
    "type": "google",
    "title": "Google HYBRID",
    "name": "HYBRID",
    "source": "google",
    "group": "background",
    "visibility": false
}
```

#### OSM

example:

```
{
    "type": "osm",
    "title": "Open Street Map",
```

```
"name": "mapnik",
    "source": "osm",
    "group": "background",
    "visibility": true
}
```

#### TileProvider

TileProvider is a shortcut to easily configure many different layer sources. It's enough to add provider property and 'tileprovider' as type property to the layer configuration object. provider should be in the form of ProviderName.VariantName.

i.e.

```
{
    "type": "tileprovider",
    "title": "Title",
    "provider": "Stamen.Toner", // "ProviderName.VariantName"
    "name": "Name",
    "group": "GroupName",
    "visibility": false
}
```

Options passed in configuration object, if already configured by TileProvider, will be overridden.

Openlayers' TileProvider at the moment doesn't support minZoom configuration property and high resolution map.

In case of missing provider or if provider: "custom", the tile provider can be customized and configured internally. You can configure the url as a template, than you can configure options add specific options (maxNativeZoom, subdomains).

```
{
    "type": "tileprovider",
    "title": "Title",
    "provider": "custom", // or undefined
    "name": "Name",
    "group": "GroupName",
```

```
"visibility": false,
"url": "https://{s}.tile.openstreetmap.org/{z}/{x}/{y}.png",
"options": {
        "subdomains": [ "a", "b"]
    }
}
```

PROVIDERS AND VARIANTS

This is a *not maintained* list of providers and variants. For the most updated list check the code here

Some of them may need some additional configuration or API keys.

OpenStreetMap.Mapnik OpenStreetMap.BlackAndWhite OpenStreetMap.DE OpenStreetMap.France OpenStreetMap.HOT Thunderforest.OpenCycleMap Thunderforest.Transport Thunderforest.TransportDark Thunderforest.Landscape Thunderforest.Outdoors OpenMapSurfer.Roads OpenMapSurfer.AdminBounds OpenMapSurfer.Grayscale Hydda.Full Hydda.Base Hydda.RoadsAndLabels MapQuestOpen.OSM MapQuestOpen.Aerial MapQuestOpen.HybridOverlay Stamen.Toner Stamen.TonerBackground Stamen.TonerHybrid Stamen.TonerLines Stamen.TonerLabels Stamen.TonerLite Stamen.Watercolor Stamen.Terrain Stamen.TerrainBackground Stamen.TopOSMRelief Stamen.TopOSMFeatures Esri.WorldStreetMap Esri.DeLorme

#### Vector

The layer type vector is the type used for imported data (geojson, shapefile) or for annotations. Generally speaking, any vector data added directly to the map. This is the typical fields of a vector layer

```
"type":"Point",
                "coordinates":[
                12.516431808471681
                41.89817370656741
                1
            },
            "properties":{
            },
            "id":0
        }
    ],
    "style":{
        "weight":5,
        "radius":10,
        "opacity":1,
        "fillOpacity":0.1,
        "color":"rgba(0, 0, 255, 1)",
        "fillColor":"rgba(0, 0, 255, 0.1)"
    },
    "hideLoading":true
}
```

- features : features in GeoJSON format.
- style : the style object.
- styleName : name of a style to use (e.g. "marker").
- hideLoading : boolean. if true, the loading will not be taken into account.

#### **WFS Layer**

A vector layer, whose data source is a WFS service. The configuration has properties in common with both WMS and vector layers. it contains the search entry that allows to browse the data on the server side. The styling system is the same of the vector layer.

This layer differs from the "vector" because all the loading/filtering/querying operations are applied directly using the WFS service, without storing anything locally.

```
{
    "type":"wfs",
    "search":{
        "url":"https://myserver.org/geoserver/wfs",
```

```
"type":"wfs"
},
"name":"workspace:layer",
"styleName":"marker",
"url":"https://myserver.org/geoserver/wfs"
}
```

### **Vector Style**

The vector and wfs layer types are rendered by the client as GeoJSON features and it possible to apply specific symbolizer using the style property available in the layer options. The style object is composed by these properties

- format the format encoding used by style body
- body the actual style rules and symbolizers

example:

```
{
  "type": "vector",
  "features": [],
  "style": {
    "format": "geostyler",
    "body": {
      "name": "My Style",
      "rules": [
        {
          "name": "My Rule",
          "symbolizers": [
            {
              "kind": "Line",
              "color": "#3075e9",
              "opacity": 1,
              "width": 2
            }
          ]
       }
      1
   }
 }
}
```

The default format used by MapStore is "geostyler" that is an encoding based on the geostyler-style specification that could include some variations or limitations related to the map libraries used by MapStore app. We suggest to refer to following doc for the rule/symbolizer properties available in MapStore.

Ths style body is composed by following properties:

- name style name
- rules list of rule object that describe the style

A rule object is composed by following properties:

- name rule name that could be used to generate a legend
- filter filter expression
- symbolizers list of symbolizer object that describe the rule (usually one per rule)

The filter expression define with features should be rendered with the symbolizers listed in the rule

example:

```
// simple comparison condition structure
// [operator, property key, value]
{
    "filter": ["==", "count", 10]
}
// mulitple condition with logical operato
// [logical operator, [condition], [condition]]
{
    "filter": [
        "||",
        [">", "height", 10],
        ["==", "category", "building"]
    ]
}
```

Available logical operators:

Operator	Description
X [ X ]	OR operator
&&	AND operator

### Available comparison operators:

Operator	Description
==	equal to
*=	like (for string type)
!=	is not
<	less than
<=	less and equal than
>	grater than
>=	grater and equal than

The symbolizer could be of following kinds:

• Mark symbolizer properties

Property	Description	2D	3D
kind	must be equal to <b>Mark</b>	x	x
color	fill color of the mark	х	x
fillOpacity	fill opacity of the mark	х	x
strokeColor	stroke color of the mark	x	x
stroke0pacity	stroke opacity of the mark	х	x
strokeWidth	stroke width of the mark	х	х
radius	radius size in px of the mark	х	x
wellKnownName	rendered shape, one of Circle, Square, Triangle, Star, Cross, X, shape://vertline, shape://horline, shape://slash, shape://backslash, shape://dot, shape://plus, shape://times, shape://oarrow or shape://carrow	X	X
msBringToFront	this boolean will allow setting the <b>disableDepthTestDistance</b> value for the feature. This would		х
msHeightReference	reference to compute the distance of the point geometry, one of <b>none</b> , <b>ground</b> or <b>clamp</b>		x
msHeight	height of the point, the original geometry is applied if undefined		x
msLeaderLineColor	color of the leading line connecting the point to the terrain		х
msLeaderLineOpacity	opacity of the leading line connecting the point to the terrain		Х
msLeaderLineWidth	width of the leading line connecting the point to the terrain		х

### • Icon symbolizer properties

Property	Description	2D	3D
kind	must be equal to <b>Icon</b>	x	x
image	url of the image to use as icon	x	x
size	size of the icon	x	x
opacity	opacity of the icon	x	x
rotate	rotation of the icon	x	х
msBringToFront	this boolean will allow setting the <b>disableDepthTestDistance</b> value for the feature. This would		x
msHeightReference	reference to compute the distance of the point geometry, one of <b>none</b> , <b>ground</b> or <b>clamp</b>		x
msHeight	height of the point, the original geometry is applied if undefined		x
msLeaderLineColor	color of the leading line connecting the point to the terrain		x
msLeaderLineOpacity	opacity of the leading line connecting the point to the terrain		x
msLeaderLineWidth	width of the leading line connecting the point to the terrain		x

• Line symbolizer properties

Property	Description	2D	3D
kind	must be equal to <b>Line</b>	x	x
color	stroke color of the line	x	x
opacity	stroke opacity of the line	x	x
width	stroke width of the line	x	x
dasharray	array that represent the dashed line intervals	x	x
msClampToGround	this boolean will allow setting the <b>clampToGround</b> value for the feature. This would only apply on Cesium maps.		х

• Fill symbolizer properties

Property	Description	2D	3D
kind	must be equal to <b>Fill</b>	х	x
color	fill color of the polygon	х	x
fillOpacity	fill opacity of the polygon	х	x
outlineColor	outline color of the polygon	х	x
outlineOpacity	outline opacity of the polygon	Х	x
outlineWidth	outline width of the polygon	Х	x
msClassificationType	allow setting <b>classificationType</b> value for the feature. This would only apply on polygon graphics in Cesium maps.		x
msClampToGround	this boolean will allow setting the <b>clampToGround</b> value for the feature. This would only apply on Cesium maps.		х

• Text symbolizer properties

Property	Description	2D	3D
kind	must be equal to <b>Text</b>	х	х
label	text to show in the label, the {{propertyKey}} notetion allow to access feature properties (eg. 'feature name is {{name}}')	х	х
font	array of font family names	х	х
size	font size of the label	х	х
fontStyle	font style of the label: normal or italic	x	x
fontWeight	font style of the label: normal or bold	х	x
color	font color of the label	х	x
haloColor	halo color of the label	х	х
haloWidth	halo width of the label	х	x
offset	array of x and y values offset of the label	x	x
msBringToFront	this boolean will allow setting the <b>disableDepthTestDistance</b> value for the feature. This would		Х
msHeightReference	reference to compute the distance of the point geometry, one of <b>none</b> , <b>ground</b> or <b>clamp</b>		Х
msHeight	height of the point, the original geometry is applied if undefined		х
msLeaderLineColor	color of the leading line connecting the point to the terrain		Х
msLeaderLineOpacity	opacity of the leading line connecting the point to the terrain		Х
msLeaderLineWidth	width of the leading line connecting the point to		х

• Model symbolizer properties (custom symbolizer to visualize 3D model as point geometries)

Property	Description	2D	3D
kind	must be equal to <b>Model</b>		х
model	url of a 3D .glb file		x
heading	heading rotation		x
pitch	pitch rotation		x
roll	roll rotation		x
scale	scale factor		x
color	color mixed with the mesh texture/material		x
opacity	color opacity		x
msHeightReference	reference to compute the distance of the point geometry, one of <b>none, ground</b> or <b>clamp</b>		х
msHeight	height of the point, the original geometry is applied if undefined		x
msLeaderLineColor	color of the leading line connecting the point to the terrain		x
msLeaderLineOpacity	opacity of the leading line connecting the point to the terrain		x
msLeaderLineWidth	width of the leading line connecting the point to the terrain		x

### Legacy Vector Style (deprecated)

The style or styleName properties of vector layers (wfs, vector...) allow to apply a style to the local data on the map.

- style : a style object/array. It can have different formats. In the simplest case it is an object that uses some leaflet-like style properties:
- weight : width in pixel of the border / line.
- radius : radius of the circle (valid only for Point types)
- opacity : opacity of the border / line.
- color : color of the border / line.
- fill0pacity : opacity of the fill if any. (Polygons, Point)
- fillColor : color of the fill, if any. (Polygons, Point)
- styleName : if set to marker, the style object will be ignored and it will use the default marker.

In case of vector layer, style can be added also to the specific features. Other ways of defining the style for a vector layer have to be documented.

### Advanced Vector Styles (deprecated)

To support advanced styles (like multiple rules, symbols, dashed lines, start point, end point) the style can be configured also in a different format, as an array of objects and you can define them feature by feature, adding a "style" property.

#### Warning

This advanced style functionality has been implemented to support annotations, at the moment this kind of advanced style options is supported **only** as a property of the single feature object, not as global style.

SVG SYMBOL (DEPRECATED)

The following options are available for a SVG symbol.

- symbolUr1 : a URL (also a data URL is ok) for the symbol to use (SVG
  format). You can anchor the symbol using:
- iconAnchor : array of x,y position of the offset of the symbol from top left corner.
- anchorXUnits, anchorYUnits unit of the iconAnchor (fraction or pixels).
- size : the size in pixel of the square that contains the symbol to draw. The size is used to center and to cut the original svg, so it must fit the svg.
- dashArray : Array of line, space size, in pixels. ["6","6"] Will draw the border of the symbol dashed. It is applied also to a generic line or polygon geometry.

MARKERS AND GLYPHS (DEPRECATED)

These are the available options for makers. These are specific of annotations for now, so allowed values have to be documented.

- iconGlyph:e.g. "shopping-cart"
- iconShape:e.g. "circle"
- iconColor:e.g. "red"
- iconAnchor:[0.5,0.5]

MULTIPLE RULES AND FILTERING (DEPRECATED)

In order to support start point and end point symbols, you could find in the style these entries:

- geometry : "endPoint"|"startPoint", identify how to get the geometry from
- filtering : if true, the geometry filter is applied.

### Example (deprecated)

Here an example of a layer with:

- · a point styled with SVG symbol,
- a polygon with dashed style
- · a line with start-end point styles as markers with icons

```
{
        "type": "vector",
        "visibility": true,
        "id": "styled-vector-layer",
        "name": "styled-vector-layer",

```

### Graticule

i.e.

```
{
    "type": "graticule",
    "labels": true,
    "frame": true, // adds a frame to the map, to better
```

```
highlight labels
    "frameRatio": 0.07, // frame percentage size (7%)
    "style": { // style for the grid lines
        "color": "#000000",
        "weight": 1,
        "lineDash": [0.5, 4],
        "opacity": 0.5
    },
    "frameStyle": { // style for the optional frame
        "color": "#000000",
        "weight": 1,
        "fillColor": "#FFFFFF"
    },
    "labelXStyle": { // style for X coordinates labels
        "color": "#000000",
        "font": "sans-serif",
        "fontWeight": "bold",
        "fontSize": "20",
        "labelOutlineColor": "#FFFFFF",
        "labelOutlineWidth": 2
    },
    "labelYStyle": { // style for Y coordinates labels
        "color": "#000000",
        "font": "sans-serif".
        "fontWeight": "bold",
        "fontSize": "20",
        "labelOutlineColor": "#FFFFFF",
        "labelOutlineWidth": 2,
        "rotation": 90,
        "verticalAlign": "top",
        "textAlign": "center"
    }
}
```

### 3D tiles

This type of layer shows 3d tiles version 1.0 inside the Cesium viewer. This layer will not be visible inside 2d map viewer types: openlayer or leaflet. See specification for more info about 3d tiles here.

i.e.

```
{
    "type": "3dtiles",
    "url": "http..." // URL of tileset.json file
```

```
"title": "3D tiles layer",
    "visibility": true,
    // optional
    "heightOffset": 0, // height offest applied to the complete
tileset
    "style": {
        "format": "3dtiles",
        "body": { // 3d tiles style
        "color": "color('#43a2ca', 1)"
        }
    }
}
```

The style body object for the format 3dtiles accepts rules described in the 3d tiles styling specification version 1.0 available here.

### Terrain

terrain layer allows the customization of the elevation profile of the globe mesh in the Cesium 3d viewer. Currently Mapstore supports three different types of terrain providers. If no terrain layer is defined the default elevation profile for the globe would be the ellipsoid that provides a rather flat profile.

The other two available terrain providers are the wms (that supports DDL/BIL types of assets) and the cesium (that support resources compliant with the Cesium terrain format).

In order to create a wms based mesh there are some requirements that need to be fulfilled:

- a GeoServer WMS service with the DDS/BIL plugin
- A WMS layer configured with **BIL 16 bit** output in **big endian mode** and **-9999 nodata value**
- BILTerrainProvider is used to parse wms based mesh. Supports three ways in parsing the metadata of the layer
  - a. Layer configuration with **sufficient metadata** of the layer. This prevents a call to getCapabilities eventually improving performance of the parsing of the layer. Mandatory fields are url, name, crs.

```
{
   "type": "terrain",
   "provider": "wms",
   "url": "http://hot-sample/geoserver/wms",
   "name": "workspace:layername",
   "littleEndian": false,
   "visibility": true,
   "crs": "CRS:84" // Supports only CRS:84 | EPSG:4326 |
EPSG:3857 | OSGE0:41001
}
```

b. Layer configuration of geoserver layer with layer name *prefixed with workspace*, then the getCapabilities is requested only for that layer

```
{
   "type": "terrain",
   "provider": "wms",
   "url": "https://host-sample/geoserver/wms", //
   'geoserver' url
   "name": "workspace:layername", // name of the geoserver
   resource with workspace prefixed
   "littleEndian": false
}
```

c. Layer configuration of geoserver layer with layer name *not prefixed with workspace* then getCapabilities is requested in global scope.

```
{
    "type": "terrain",
    "provider": "wms",
    "url": "https://host-sample/geoserver/wms",
    "name": "layername",
    "littleEndian": false
}
```

#### 🖍 Note

With wms as provider, the format option is not needed, as Mapstore supports only image/bil format and is used by default

Generic layer configuration of type terrain and provide wms as follows. The layer configuration needs to point to the geoserver resource and define the type of layer and the type of provider, here all available properties:

```
{
  "type": "terrain",
  "provider": "wms",
  "url": "https://host-sample/geoserver/wms",
  "name": "workspace:layername", // name of the geoserver
resource
 "littleEndian": false, // defines whether buffer is in little
or big endian
 "visibility": true,
  // optional properties
  "crs": "CRS:84", // projection of the layer, support only CRS:
84 | EPSG:4326 | EPSG:3857 | OSGEO:41001
  "version": "1.3.0", // version used for the WMS request
  "heightMapWidth": 65, // width of a tile in pixels, default
value 65
  "heightMapHeight": 65, // height of a tile in pixels, default
value 65
  "waterMask": false,
  "offset": 0, // offset of the tiles (in meters)
  "highest": 12000, // highest altitude in the tiles (in meters)
  "lowest": -500, // lowest altitude in the tiles
  "sampleTerrainZoomLevel": 18 // zoom level used to perform
sampleTerrain and get the height value given a point, used by
measure components
}
```

The terrain layer of cesium type allows using Cesium terrain format compliant services (like Cesium Ion resources or MapTiler meshes). The options attributte allows for further customization of the terrain properties (see available options on the Cesium documentation for the cesium terrain provider)

```
{
    "type": "terrain",
    "provider": "cesium",
    "url": "https://terrain-provider-service-url/?key={apiKey}",
    "visibility": true,
    "options": {
        // requestVertexNormals, requestWatermask, credit...
```

} }

In order to use these layers they need to be added to the additionalLayers in localConfig.json. The globe only accepts one terrain provider so in case of adding more than one the last one will take precedence and be used to create the elevation profile.

```
{
    "name": "Map",
    "cfg": {
        "additionalLayers": [{
            "type": "terrain",
            "provider": "wms",
            "url": "https://host-sample/geoserver/wms",
            "name": "workspace:layername", // name of the
geoserver resource
        "littleEndian": false,
        "visibility": true,
        "crs": "CRS:84"
      }]
    }
}
```

# Layer groups

Inside the map configuration, near the layers entry, you can find also the groups entry. This array contains information about the groups in the TOC. A group entry has this shape:

- id : the id of the group.
- expanded : boolean that keeps the status (expanded/collapsed) of the group.
- title : a string or an object (for i18n) with the title of the group. i18n object format is the same of layer's title.

```
"title": {
    "default": "Root Group",
```

```
"it-IT": "Gruppo radice",
    "en-US": "Root Group",
    "de-DE": "Wurzelgruppe",
    "fr-FR": "Groupe Racine",
    "es-ES": "Grupo Raíz"
},
```

i.e.

```
{
  "id": "GROUP_ID",
  "title": "Some default title"
  "expanded": true
}
```

# Other supported formats

The JSON format above is the standard MapStore format. Anyway MapStore allows to import/export different kinds of formats for maps.

# Web Map Context

MapStore provides support for OGC Web Map Context(WMC) files. They can be imported either using Import plugin functionality, or from within a context using Map Templates plugin. MapStore maps can also be exported in WMC format through Export plugin.

The important thing to remember when exporting MapStore maps to WMC format is that it only supports WMS layers, meaning any non-WMS layers(such as tiled OSM backgrounds for example) will not be preserved in the resulting WMC file. The exact way in which the conversion happens is described in further detail throughout this document.

### WMC File Structure

WMC context file generated by MapStore is an XML file with the following structure:

```
<?xml version="1.0" encoding="UTF-8"?>
<ViewContext xmlns="http://www.opengis.net/context"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
version="1.1.0" xsi:schemaLocation="http://www.opengis.net/
context http://schemas.opengis.net/context/1.1.0/context.xsd">
    <General>
        <Title>MapStore Context</Title>
        <Abstract>This is a map exported from MapStore2.</
Abstract>
        <BoundingBox minx="-20037508.34" miny="-20037508.34"</pre>
maxx="20037508.34" maxy="20037508.34" SRS="EPSG:900913"/>
        <Extension>
            <!--general extensions go here-->
        </Extension>
    </General>
    <LaverList>
        <Layer queryable="0" hidden="0">
        <Name>topp:states</Name>
        <Title>USA Population</Title>
        <Server service="OGC:WMS" version="1.3.0">
            <OnlineResource xmlns:xlink="http://www.w3.org/1999/</pre>
xlink" xlink:type="simple" xlink:href="https://demo.geo-
solutions.it/geoserver/wms"/>
        </Server>
        <DimensionList>
            <Dimension name="elevation" units="EPSG:5030"</pre>
unitSymbol="m" default="0.0"
multipleValues="1">0.0,200.0,400.0,600.0</Dimension>
            <Dimension name="time" units="IS08601"</pre>
default="current" multipleValues="1">2016-02-23T03:00:00.000Z,
2016-02-23T06:00:00.000Z</Dimension>
            <!--...other dimensions-->
        </DimensionList>
        <FormatList>
            <Format current="1">image/png</Format>

        </FormatList>
        <StyleList>
            <Style>
                <Name>population</Name>
                <Title>Population in the United States</Title>
                <LegendURL width="81" height="80" format="image/</pre>
png">
                    <OnlineResource xmlns:xlink="http://
www.w3.org/1999/xlink" xlink:type="simple" xlink:href="https://
demo.geo-solutions.it:443/geoserver/topp/states/ows?
service=WMS&request=GetLegendGraphic&format=image%2Fpng&am
```

```
</LegendURL>
</Style>
</styleList>
</StyleList>
</StyleList>
</Extension>
</!--layer extensions go here-->
</Extension>
<!--...other layers-->
</LayerList>
</ViewContext>
```

More information about each of the elements in the example above can be looked up in OGC WMC implementation specification

Apart from standard WMC XML elements, MapStore provides support for various extensions. These are placed inside Extension tag, and are not gueranteed to be supported outside MapStore, as they are not a part of OGC Web Map Context specification. MapStore provides two types of extensions: openlayers and mapstore-specific elements. WMC can have an Extension element inside General, and each of the Layer elements. Supported extensions in General are:

Openlayers:

 maxExtent if present, it's attributes are used as map's bounding box, instead of the values specified in BoundingBox tag. The values are assumed to be in a projection, specified in SRS attribute of BoundingBox

```
<ol:maxExtent xmlns:ol="http://openlayers.org/context"
minx="-20037508.34" miny="-20037508.34" maxx="20037508.34"
maxy="20037508.34"/>
```

MapStore specific:

• GroupList defines a mapstore group list. Contains Group elements that describe a particular layer group:

```
<ms:GroupList xmlns:ms="https://mapstore.geosolutionsgroup.com/
mapstore/context">
        <ms:Group xmlns:ms="https://mapstore.geosolutionsgroup.com/
```

```
mapstore/context" id="Default" title="Default" expanded="true"/>
</ms:GroupList>
```

• center defines a center of map view

```
<ms:center xmlns:ms="https://mapstore.geosolutionsgroup.com/
mapstore/context" x="1.5" y="2.5" crs="EPSG:3857"/>
```

zoom map zoom level

```
<ms:zoom xmlns:ms="https://mapstore.geosolutionsgroup.com/
mapstore/context">7</ms:zoom>
```

Supported extensions for each Layer element are:

**Openlayers:** 

- maxExtent if present, used for the value of layer's bbox. Values are assumed to be in a projection, specified in SRS attribute of "BoundingBox"
- singleTile specifies layer's "singleTile" property value
- transparent is layer transparent or not, true by default
- isBaseLayer if true, the layer is put into "backgrounds" group
- · opacity layer's opacity value

```
<ol:maxExtent xmlns:ol="http://openlayers.org/context"
minx="-13885038.382960921" miny="2870337.130793682"
maxx="-7455049.489182421" maxy="6338174.0557576185"/>
<ol:singleTile xmlns:ol="http://openlayers.org/context">false</
ol:singleTile xmlns:ol="http://openlayers.org/context">false</
ol:singleTile>
<ol:transparent xmlns:ol="http://openlayers.org/context">false</
ol:transparent xmlns:ol="http://openlayers.org/context">false</
ol:transparent xmlns:ol="http://openlayers.org/context">false</
ol:transparent xmlns:ol="http://openlayers.org/context">false</
ol:transparent xmlns:ol="http://openlayers.org/context">false</
ol:transparent xmlns:ol="http://openlayers.org/context">false</
ol:transparent>
<ol:transparent>
```

Cesium:

 tileDiscardPolicy sets a policy for discarding (missing/broken) tiles (https://cesium.com/learn/cesiumjs/ref-doc/TileDiscardPolicy.html). If it is not specified the NeverTileDiscardPolicy will be used. If "none" is specified, no policy at all will be set.

MapStore specific:

- group specifies to which group, among listed in "GroupList" element, the layer belongs to
- search JSON describing a filter that is applied to the layer
- DimensionList contains Dimension elements that describe dimensions that cannot be described using standard "Dimension" tag. Currently supports dimensions of *multidim-extension* type:
- CatalogServices contains Service elements that describe services available for use in Catalog.

```
<ms:DimensionList xmlns:ms="https://
mapstore.geosolutionsgroup.com/mapstore/context">
            <ms:Dimension <pre>xmlns:ms="https://
mapstore.geosolutionsgroup.com/mapstore/context"
xmlns:xlink="http://www.w3.org/1999/xlink" name="time"
type="multidim-extension" xlink:type="simple"
xlink:href="https://cloudsdi.geo-solutions.it/geoserver/gwc/
service/wmts"/>
</ms:DimensionList>
<ms:CatalogServices selectedService="gs_stable_csw">
            <ms:Service serviceName="gs_stable_csw">
                        <ms:Attribute name="url" type="string">https://gs-
stable.geosolutionsgroup.com/geoserver/csw</ms:Attribute>
                        <ms:Attribute name="type" type="string">csw<///rights//ri
ms:Attribute>
                        <ms:Attribute name="title" type="string">GeoSolutions
GeoServer CSW</ms:Attribute>
                        <ms:Attribute name="autoload" type="boolean">true
ms:Attribute>
            </ms:Service>
            <ms:Service serviceName="gs_stable_wms">
                        <ms:Attribute name="url" type="string">https://gs-
stable.geosolutionsgroup.com/geoserver/wms</ms:Attribute>
                        <ms:Attribute name="type" type="string">wms<///right</pre>
```

```
ms:Attribute>
       <ms:Attribute name="title" type="string">GeoSolutions
GeoServer WMS</ms:Attribute>
        <ms:Attribute name="autoload" type="boolean">false
ms:Attribute>
    </ms:Service>
    <ms:Service serviceName="gs_stable_wmts">
        <ms:Attribute name="url" type="string">https://gs-
stable.geosolutionsgroup.com/geoserver/gwc/service/wmts<//r>
ms:Attribute>
        <ms:Attribute name="type" type="string">wmts<///r>
ms:Attribute>
       <ms:Attribute name="title" type="string">GeoSolutions
GeoServer WMTS</ms:Attribute>
        <ms:Attribute name="autoload" type="boolean">false
ms:Attribute>
    </ms:Service>
</ms:CatalogServices>
```

Note, that during the exporting process, some sort of fallback for dimensions, listed as extensions, is provided inside the standard DimensionList tag whenever possible, to ensure interoperability with other geospatial software. When such a context is imported back into MapStore, the values of dimensions inside extensions will override the ones specified inside the standard DimensionList tag.

Also note, that the extension elements would be read correctly only if they belong to appropriate XML namespaces:

- http://openlayers.org/context for openlayers extensions
- https://mapstore.geosolutionsgroup.com/mapstore/context for mapstore specific extensions

### Usage inside MapTemplates plugin

As stated previously, WMC files can be used as map templates inside contexts. New WMC templates can be uploaded in context creation tool, after enabling the MapTemplates plugin for a context. When the context is loaded, for every template inside MapTemplates there are two options available:

• Replace map with this template replace the currently loaded map with the one described by the template. Upon loading, the map will zoom to the

extent specified in maxExtent extension or in BoundingBox tag. If the template has no visible background layers available, the default empty background will be added and set to be visible automatically.

 Add this template to map merges layers and groups inside the template with the current map configuration. If the WMC template does not contain GroupList extension, a new group with the name extracted from Title tag of the template will be created and will contain all the layers of the template. Zoom and projection will remain unchanged.

#### **Other considerations**

Due to the limitations posed by WMC format the conversion process will not preserve the map state in it's entirety. The only supported way to do this is to export to MapStore JSON format. The WMC export option presumably should be used in cases when the WMS layers inside a MapStore map need to be used in some way with a different geospatial software suite, or to import such layers from outside MapStore or if you already have WMC context files that you want to use.

# Additional map configuration options

Map configuration also contains the following additional options:

- catalogServices object describing services configuration for Catalog
- widgetsConfig configuration of map widgets
- mapInfoConfiguration map info configuration options
- dimensionData contains map time information
- currentTime currently selected time; the beginning of a time range if offsetTime is set
- offsetTime the end of a time range
- timelineData timeline options
- selectedLayer selected layer id; if not present time cursor will be unlocked
- mapViews map views options

### mapViews

### Example:

{

```
"mapViews": {
  "active": true,
  "selectedId": "view.id.01",
  "views": [
    {
      "id": "view.id.01",
      "title": "Title".
      "description": "Description",
      "duration": 10,
      "flyTo": true,
      "center": {
        "longitude": 8.93690091201193,
        "latitude": 44.39522451776296,
        "height": -0.0022900843616703204
      },
      "cameraPosition": {
        "longitude": 8.93925651181738,
        "latitude": 44.38698231953802,
       "height": 655.705914040523
      },
      "zoom": 17.89659156734602,
      "bbox": [
       8.920925393119584,
       44.39084055670365,
       8.948118718933738.
       44.40554444092288
      ],
      "mask": {
       "enabled": true,
        "resourceId": "resource.id.01",
        "inverse": true,
        "offset": 10000
      },
      "terrain": {
        "clippingLayerResourceId": "resource.id.02",
        "clippingPolygonFeatureId": "feature.id.01",
        "clippingPolygonUnion": true
      },
      "globeTranslucency": {
        "enabled": true,
        "fadeByDistance": false,
```

```
"nearDistance": 500,
          "farDistance": 50000,
          "opacity": 0.5
        },
        "layers": [
          {
            "id": "layer.id.01",
            "visibility": true,
            "opacity": 0.5
          },
          {
            "id": "layer.id.04",
            "visibility": true,
            "clippingLayerResourceId": "resource.id.02",
            "clippingPolygonFeatureId": "feature.id.01",
            "clippingPolygonUnion": false
          }
        ]
      }
    ],
    "resources": [
      {
        "id": "resource.id.01",
        "data": {
          "type": "vector",
          "name": "mask",
          "title": "Mask",
          "id": "layer.id.02"
        }
      },
      {
        "id": "resource.id.02",
        "data": {
          "type": "wfs",
          "url": "/service/wfs",
          "name": "clip",
          "title": "Clip",
          "id": "layer.id.03"
        }
      }
   ]
 }
}
```

The mapViews properties

Name	Туре	Description
active	boolean	if true the map view tool will be active at initialization
selectedId	string	id of the selected view
views	array	array of views configurations (see below)
resources	array	resources configurations (see below)

View configuration object

Name	Туре	Description
id	string	identifier of the view
title	string	title of the view
description	string	an html string to describe the view
duration	number	when playing, duration in seconds of the view
fly⊤o	boolean	enable animation transition during navigation
center	object	center target position as
cameraPosition	object	point of view position as
zoom	number	zoom level
bbox	array	bounding box in WGS84 as [minx, miny, maxx, maxy]
mask	object	optional configuration for the 3D tiles mask
mask.enabled	boolean	if true enables the mask
mask.resourceld	string	identifier of a resource configuration in the resources array
mask.inverse	boolean	if true enables the inverse mask
mask.offset	number	offset in meters for the inverse mask
terrain	object	optional configurations for terrain clipping
terrain.clippingLayerResourceId	string	identifier of a resource configuration in the resources array

## Resource object configuration

Name	Туре	Description
id	string	identifier for the resource
data	object	properties related to the layer used for the resource (wfs or vector type)

# Externalized Configuration

The **data directory** is a directory on the file-system, configured for an instance of MapStore, that will be used to externalize configuration of MapStore.

Configuring this directory you will be able to:

- Externalize database configuration
- Externalize proxy configuration
- Externalize JSON configs files for the application (localConfig.json, new.json)
- Apply patches to default JSON config files (e.g. to store only the differences)
- Store extensions installed

All the configuration stored here will persist across MapSore updates.

# Using a data directory

To use a data directory, this must be configured through a specific JVM system property: datadir.location

```
java -Ddatadir.location=/etc/mapstore/datadir
```

The data-directory must exist, but all the files inside it are optional. Due to some particular operations (e.g. installation of extensions), some files may be stored in data-dir by the application itself.

The structure of the data-dir is the following:

```
.

├── configs (JSON configs)

│ └── pluginsConfig.json.patch

├── extensions

│ └── extensions.json (extensions index)
```

- configs: files in this folder can override the files in configs file of the application (pluginsConfig.json, localConfig.json).
- If a file with the same name is present, it will be provided instead of the original one
- If a patch file is present, (e.g. localConfig.json.patch) the patch will be applied to the JSON (original or overridden) and provided patched to the client
- extensions : this folder contains all the files for the installed extensions, one folder for each installed extension
- extensions.json : the index of the current extensions installed.

### Multiple data directory locations

It is possible to specify more than one datadir location path, separated by commas. This can be useful if you need to have different places for static configuration and dynamic one. A dynamic configuration file is one that is updated by MapStore using the UI, while static ones can only updated manually by an administrator of the server. An example are uploaded extensions, and their configuration files.

MapStore looks for configuration resources in these places in order:

- the first datadir.location path other datadir.location paths, if any, in order
- the application root folder

Dynamic files will always be written by the UI in the first location in the list, so the first path is for dynamic stuff.

Example:

```
-Ddatadir.location=/etc/mapstore_extensions,/etc/
mapstore_static_config
```

### Logging

Logging has not been externalized yet, You can manually do this change in WEB-INF/web.xml file to externalize also this file:

```
<context-param>
        <param-name>log4jConfigLocation</param-name>
        <param-value>file:${datadir.location}/log4j2.properties</
param-value>
</context-param>
```

### **Print Configuration**

The config.yaml is by default in the printing folder of the webapp root. You can externalize the path to this resource (and all relative files) by setting the system variable mapfish-print-config. Make you sure the file exists and all the required files (header, images ...) are also available (typically they are the same directory, identified by relative paths. For more information, see mapfish-print documentation ).

Example:

```
-Dmapfish-print-config=/etc/mapstore/datadir/printing/
config.yaml
```

We suggest to put your customizations for printing inside the data directory in a folder named printing, using the same structure of the printing folder of the application. (config.yaml, images and so on...). Doing it this way makes the application ready for future updates.

### **Database Connection**

If you create a file in the datadir called geostore-datasource-ovr.properties , it will be used and override the current

Example:

geostoreDataSource.driverClassName=org.postgresql.Driver geostoreDataSource.url=jdbc:postgresql://localhost:5432/geostore geostoreDataSource.username=geostore geostoreDataSource.password=geostore geostoreVendorAdapter.databasePlatform=org.hibernate.dialect.Postg geostoreEntityManagerFactory.jpaPropertyMap[hibernate.hbm2ddl.auto geostoreEntityManagerFactory.jpaPropertyMap[hibernate.default\_sche geostoreVendorAdapter.generateDdl=true geostoreVendorAdapter.showSql=false

## NOTE: this file simply overrides the values in geostore-datasource-

**ovr.properties** in the web-application, it will not replace it usually it is configured by default to use h2 database, so configuring the database (h2, postgreSQL or oracle) will override all the properties. Anyway if you changed this file in your project, you may need to override more variables to make it work

## Overriding front-end configuration

Externalizing the whole localConfig.json file allows to keep your configurations during the various updates. Anyway keeping this long file in sync can become hard. You can use patch files, and this is the first suggested option.

Anyway if you need to specify something in localConfig.json that comes from your Java application, MapStore gives you the possibility to override only some specific properties of this big file and keep these changes separated from the application, allowing an easier updates. This is particularly useful for example when you have to change only a bunch of settings on a specific instance, and use the standard configuration for everything else.

You can override one or more properties in the file using the following JVM flags:

- overrides.config: the path of a properties file (relative to the datadir)
   where override values are stored
- overrides.mappings: comma limited list of JSONPath=property values to override

An example of overrides that will replace the default WMS service url:

In mapstore.properties:

overrides.config=env.properties
overrides.mappings=initialState.defaultState.catalog.default.servi

In datadir\_path/env.properties:

geoserverUrl=https://demo.geo-solutions.it/geoserver/wms

This allows to have in datadir\_path/env.properties a set of variables that can be used in overrides (even in different places) that are indicated by overrides.mappings.

Note: env.properties should not be placed in classpath folder

## Patching front-end configuration

Another option is to patch the frontend configuration files, instead of overriding them completely, using a patch file in json-patch format.

To patch one of the allowed resources you can put a file with a **.patch** extension in the datadir folder (e.g. localConfig.json.patch) and that file will be merged with the main localConfig.json to produce the final resource.

This allows easier migration to a new MapStore version. Please notice that when you use a patch file, any new configuration from the newer version will be applied automatically. This can be good or bad: the good part is that new plugins and features will be available without further configuration after the migration, the bad part is that you won't be aware that new plugins and features will be automatically exposed to the final user.

Example: adding a plugin to the localConfig.json configuration file:

```
[{"op": "add", "path": "/plugins/desktop/-", "value":
"MyAwesomePlugin"}]
```

## Externalize front-end Configurations

From version 2021.02.xx, the externalization of the front-end files is automatic on the back-end, as well as you configure the data-directory. Anyway for your custom application you may want to customize the following paths to point your own services for configuration, extensions, and so on. The paths can be customized by adding the relative line in the <code>app.jsx</code> :

• Application (localConfig.json):

```
ConfigUtils.setLocalConfigurationFile("configs/
localConfig.json");
```

• Static maps (new.json and config.json):

ConfigUtils.setConfigProp("configurationFolder", "configs/");

• Extensions configuration ( extensions.json ):

```
ConfigUtils.setConfigProp("extensionsRegistry", "extensions/
extensions.json");
```

• Context Editor ( pluginsConfig.json ):

```
ConfigUtils.setConfigProp("contextPluginsConfiguration",
"configs/pluginsConfig.json");
```

• Extensions folder (folder where to get the extensions found in extensions.json):

ConfigUtils.setConfigProp("extensionsFolder", "extensions/");

🖍 Note

Because in this case we are modifying the app.jsx file, these changes can be applied only at build time in a custom project. Future improvements will allow to externalize these files also in the main product, without any need to rebuild the application.

# Configuration of Application Context Manager

The Application Context Manager can be configured editing the configs/ pluginsConfig.json file.

The configuration file has this shape:

```
{
 "plugins": [
    {
        "name": "Map",
        "mandatory": true, // <-- mandatory should not be shown
in editor OR not movable and directly added to the right list.
    }, {
        "name": "Notifications",
        "mandatory": true, // <-- mandatory should not be shown
in editor OR not movable and directly added to the right list.
              "hidden": true, // some plugins are only support,
so maybe showing them in the UI is superfluous.
    }, {
        "name": "TOC",
       "symbol": "layers",
        "title": "plugins.TOC.title",
        "description": "plugins.TOC.description",
        "defaultConfig": {},
        "children": ["TOCItemSettings", "FeatureEditor"]
    }, {
        "name": "FeatureEditor",
       "defaultConfig": {}
    }, {
        "name": "TOCItemSettings",
        . . . . . .
    }, {
        "name": "MyPlugin", // <-- this is typically an
extension,
        "docUrl": "https://domain.com/documentation" // <--
custom documentation url
    }, {
       "name": "Footer",
      "children": ["MousePosition", "CRSSelector", "ScaleBox"]
    }, {
```

The configuration contains the list of available plugins to display in the plugins selector. Each entry of plugins array is an object that describes the plugin, it's dependencies and it's properties. These are the properties allowed for the plugin entry object:

- name: {string} the name (ID) of the plugin
- title: {string} the title string OR messageld (from localization file)
- description: {string}: the description string OR messageId (from localization file)
- docUrl: {string}: the plugin/extension specific documentation url
- symbol : {string}`: icon (or image) symbol for the plugin
- defaultConfig {object} : optional object containing the default configuration to pass to the context-creator.
- mandatory {boolean} : if true, the plugin must be added to the map, so not possible to remove (but can be customized)
- hidden {boolean} : if true, the plugin should not be shown in UI. If mandatory, is added without showing.
- children {string[]}: list of the plugins names (ID) that should be shown as children in the UI
- dependencies : The difference between mandatory and dependencies is the "if the parent is present" condition.). Plugins that can not be disabled (or if are hidden, added by default) and are added ONLY if the parent plugin is

added. (e.g. containers like toolbar, omnibar, footer or DrawerMenu, and other dependencies like Widgets that must contain WidgetsBuilder and so on)

# Database Setup

MapStore can use 3 types of database:

- H2
- PostgreSQL
- Oracle

MapStore uses an H2 in-memory DB as the default DBMS to persist the data. This configuration is useful for development and test purposes, or to evaluate the project but it is obviously NOT RECOMMENDED for production usage; moreover the H2 DB cannot be used for the integration with GeoServer.

In the following guide you will learn how to configure MapStore to use an external database.

## Externalize properties files

MapStore has a file called geostore-datasource-ovr.properties. This file is on the repository in the folder java/web/src/main/resources, in the final mapstore.war package it will be copied into WEB-INF/classes path. It contains the set-up for the database connection. Anyway if you edit the file in WEB-INF/ classes this file will be overridden on the next re-deploy. To preserve your configuration on every deploy you can use an environment variable, geostoreovr, to configure the path to an override file in a different, external directory. In this file the user can re-define the default configuration and so set-up the database configuration.

For instance using tomcat on linux you will have to do something like this to add the environment variable to the JAVA\_OPTS

where to add your JAVA\_OPTS depends on your operating system. For instance the file could be /etc/default/tomcat8, or similar, in linux debian

```
# here the path to the ovr file
GEOSTORE_OVR_FILE=file:///var/lib/tomcat/conf/geostore-
ovr.properties
# add the serve we sightly be added as the LAVA_OPTO
```

# add the env. variable 'geostore-ovr' to JAVA\_OPTS
JAVA\_OPTS="-Dgeostore-ovr=\$GEOSTORE\_OVR\_FILE [other opts]"

So your file /var/lib/tomcat/conf/geostore-ovr.properties will contain the overrides to the database set-up.

## Database creation Mode

By default MapStore automatically populates the database on it's own. If you want to disable this functionality (e.g. if you don't want to allow the database user to have permission to create tables) then you have to set-up the following property in the ovr file to 'validate'

geostoreEntityManagerFactory.jpaPropertyMap[hibernate.hbm2ddl.auto

Options are:

- validate : validate the schema, makes no changes to the database.
- update : update the schema.
- create : creates the schema, destroying previous data.
- create-drop : drop the schema when the SessionFactory is closed explicitly, typically when the > application is stopped.

In this case it is necessary to manually create the required tables using the scripts available here for the needed DBMS.

The update mode is usually discouraged in production. On production servers you should always use validate mode and apply SQL scripts and/or patches manually. Anyway before every update a database backup is strongly suggested.

If you download or build mapStore.war, it's default configuration will be this one:

```
geostoreDataSource.url=jdbc:h2:./webapps/mapstore/geostore
geostoreEntityManagerFactory.jpaPropertyMap[hibernate.hbm2ddl.auto
```

This configuration creates a file called geostore in the webapp folder. You can change the geostoreDataSource.url to set the path to the database you want to use. Make you sure that the user of the project that executes Tomcat has write permissions on the folder where you want to create the database.

## PostgreSQL

All the following configurations will use geostore as password of the user geostore. Of course you can change it according to your needings.

### Database Creation and Setup

To use postgreSQL DBMS as MapStore you have to create the "geostore" DB.

- Log in as user postgres
- Create the geostore DB:

createdb geostore

Create users and schemas:

```
psql geostore < 001_setup_db.sql</pre>
```

Here below the required part of the file 001\_setup\_db.sql, available here (creation of test user and schema for geostore\_test in the original file is not strictly required for MapStore) Write the password you prefer instead of 'geostore'

```
-- CREATE SCHEMA geostore (set the password you prefer)
CREATE user geostore LOGIN PASSWORD 'geostore' NOSUPERUSER
INHERIT NOCREATEDB NOCREATEROLE;
CREATE SCHEMA geostore;
GRANT USAGE ON SCHEMA geostore TO geostore ;
GRANT ALL ON SCHEMA geostore TO geostore ;
alter user geostore set search_path to geostore , public;
```

If you need to create the database schema manually (validate mode), you have also this script.

At the end, **make you sure that the user** geostore **has access to the database** from the address of MapStore application. You can give permission by editing pg\_hba.conf

### Connection to the Database

To configure MapStore to connect it to the new created database you have to edit your override file like below (change the connection parameters accordingly):

```
# Setup driver and dialect for PostgreSQL database
geostoreDataSource.driverClassName=org.postgresql.Driver
geostoreVendorAdapter.databasePlatform=org.hibernate.dialect.Postg
# Connection parameters
geostoreDataSource.url=jdbc:postgresql://localhost:5432/geostore
geostoreDataSource.username=geostore
geostoreDataSource.password=geostore
geostoreEntityManagerFactory.jpaPropertyMap[hibernate.default_sche
# Automatic create-update database mode
geostoreEntityManagerFactory.jpaPropertyMap[hibernate.hbm2ddl.auto
# Other options
geostoreVendorAdapter.generateDdl=true
geostoreVendorAdapter.showSql=false
```

### Migrate an existing H2 database to PostgreSQL

If you used an H2 database during development, and you want to deploy the application in production, migrating the database to PostgreSQL is not that easy.

For this reason we have created a specific tool for this task, called **H2ToPgSQLExport** that is part of the GeoStore CLI.

More information on the migration tool is available in the GeoStore CLI documentation page.

## Oracle

### Database Creation and Setup

Create a database geostore, a schema called GEOSTORE and a user geostore that has write access to them.

Use this SQL script to create the DB schema.

### Connection to the Database

To configure MapStore to connect to the new created database you have to edit your override file like reported below:

```
# Setup driver and dialect for Oracle Database
geostoreDataSource.driverClassName=oracle.jdbc.OracleDriver
geostoreVendorAdapter.databasePlatform=org.hibernate.dialect.Oracl
# Connection parameters
geostoreDataSource.url=jdbc:oracle:thin:@localhost:1521/ORCL
geostoreEntityManagerFactory.jpaPropertyMap[hibernate.default_sche
geostoreDataSource.username=geostore
geostoreDataSource.password=geostore
# Automatic create-update database mode
geostoreEntityManagerFactory.jpaPropertyMap[hibernate.hbm2ddl.auto
# Other options
```

```
geostoreVendorAdapter.generateDdl=true
geostoreVendorAdapter.showSql=false
```

# GeoServer integrations

## MapStore/GeoServer users integration

MapStore can share users, groups an roles with GeoServer. This type of integration allows to setup a fine grained access to the data and the services based on MapStore groups and roles.

This guide explains how to share users, groups and roles between MapStore and GeoServer. Applying this configurations will allow users logged in MapStore to be recognized by GeoServer. So security rules about restrictions on services, layers and so on can be correctly applied to MapStore users (also using GeoFence).

With the suggested implementation the MapStore database will be also a UserGroupService and a RoleService for GeoServer. This means that every user of MapStore will be also a user in GeoServer, with the same attributes, the same roles (ADMIN, USER) and the same user groups.

For every user-group assigned to a user GeoServer will see also **a role** of the same name, from the role service, assigned to the members of the user-group (as user-group derived roles).

Permission on GeoServer can be assigned using these roles or with more detailed granularity using a custom Resource Access Manager (like GeoFence).

## Limits of this solution

This solution partially degradates the functionalities of user management UI of GeoServer (for users, groups and roles that belong to MapStore). If you want to use this solution, you should use the MapStore's user manager and avoid the GeoServer's one.

## Requirements

- 1. GeoServer must have the Authkey Plugin Community Module installed
- 2. MapStore2 Database must be reachable by GeoServer (H2 will not work, use PostgreSQL or Oracle)
- 3. MapStore2 must be reachable by GeoServer via HTTP

This example will focus on **PostgreSQL** database type I am assuming this is a new installation, so no existing user or map will be preserved

## Database preparation

1. Follow Geostore wiki to setup a postgresql database (ignore the geostore\_test part)

- 2. Start your Tomcat at least once, so mapstore.war will be extracted in the webapps directory of tomcat instance.
- 3. Stop Tomcat.
- 4. Copy from the extracted folder ( <TOMCAT\_DIR>/webapps/mapstore ) the file located at WEB-INF/classes/db-conf/postgres.properties to replace the file WEB-INF/classes/geostore-database-ovr.properties.
- 5. Edit the new WEB-INF/classes/geostore-database-ovr.properties file with your DB URL and credentials.
- 6. Start Tomcat

#### Default user password couples are

- admin:admin
- user:user

### GeoServer Setup

#### Follow this guide

Create the empty GeoStore database using scripts as described in GeoStore WIKI.

The following procedure will make GeoServer accessible to users stored in the MapStore database. In case of the users on MapStore and GeoServer have the same name, the users of MapStore will have precedence. At the end of the procedure, if you access with the user admin, you will have to use the password of the admin user of MapStore ( admin by default).

#### User Groups and Roles

Steps below reference user, group and role service configuration files, as needed download the files from the geostore repository.

#### **Setup User Group Service**

- In GeoServer, Open the page "Security" --> "User Groups Roles" (from the left menu)
- In the section "User Group Services" click on "add new" to a new user group service
- Select JDBC
- name: geostore
- Password encryption : Digest
- password policy default
- Driver org.postgresql.Driver (or JNDI)
- connection url jdbc:postgresql://localhost:5432/geostore (or the one for your setup)
- JNDI only: the JNDI resource name should look like this java:comp/env/ jdbc/geostore
- set username and password for the db (user geostore with password geostore)
- click on "Save" button
- Then, in order to adapt the standard JDBC service to MapStore database, you must place the provided files in the new directory (created by GeoServer for this new user group service) inside the data directory at the following path <gs\_datadir>/security/usergroup/geostore. (geostore is the name of the new user group service)
- Then go back to geostore user group service page in GeoServer (the ddl and dml path should have values in them)
- click on "Save" button again

#### **Setup Role Service**

- In GeoServer Open the page "Security" --> "User Groups Roles" (from the left menu)
- In the section "Role Services" click on "add new" to a new role service

- select JDBC
- name geostore
- db org.postgresql.Driver
- connection url: jdbc:postgresql://localhost:5432/geostore (or JNDI, same as above)
- set user and password (user geostore with password geostore)
- click on "Save" button
- add the provided files to the geostore directory under /<gs\_datadir>/ security/role/geostore
- click on "Save" button again
- go Again in JDBC Role Service geostore
- select Administrator role to ADMIN
- select Group Administrator Role to ADMIN

#### Use these services as default

- In GeoServer "Security" --> "Settings" section (from the left menu)
- Set the Active role service to geostore
- go to Authentication Section, scroll to Authentication Providers and Add a new one.
- select 'Username Password'
- name it "geostore"
- · select "geostore" from the select box
- Save.
- Then go to "Provider chain" and move geostore on top in the right list.
- Save again

### Use the Auth key Module with GeoStore/GeoServer

These last steps are required to allow users logged in MapStore to be authenticated correctly by GeoServer.

#### **Configure GeoServer**

- Install the authkey module in GeoServer if needed (most recent versions of GeoServer already include it).
- Go to the authentication page and scroll into the 'Authentication Filters' section
- · Click 'Add new'.
- Inside the 'New authentication Filter' page click on authkey module.
- Insert the name (i.e. 'geostore').
- Leave authkey as parameter name.
- · Select the Web Service as 'Authentication key user mapper'.
- · Select the created geostore's 'User/Group Service'.
- Input the mapstore2 url: http://<your\_hostname>:<mapstore2\_port>/
  mapstore/rest/geostore/session/username/{key}. Examples:

```
http://localhost:36728/mapstore/rest/geostore/session/username/
{key}
http://localhost/mapstore2/rest/geostore/session/username/{key}
http://mapstore.geosolutionsgroup.com/mapstore/rest/geostore/
session/username/{key}
```

#### • Save.

- Go into the authentication page and open default filter chain.
- Add 'geostore' into the 'Selected' filters and put it on top, and save.

Note

in the User Groups and Roles Services available options there are "AuthKEY WebService Body Response - UserGroup Service from WebService Response Body" and "AuthKEY REST - Role service from REST endpoint". Ignore them as they are not supported from MapStore2.

#### **Configure MapStore**

The last step is to configure MapStore to use the authkey with the configured instance of GeoServer. You can do it by adding to localConfig.json like this:

```
//...
"useAuthenticationRules": true,
    "authenticationRules": [{
        "urlPattern": ".*geostore.*",
        "method": "bearer"
    }, {
        "urlPattern": "\\/geoserver/.*",
        "authkeyParamName": "authkey",
        "method": "authkey"
    }],
//...
```

- Verify that "useAuthenticationRules" is set to true
- authenticationRules array should contain 2 rules:
  - The first rule should already be present, and defines the authentication method used internally in mapstore
  - The second rule (the one you need to add) should be added and defines how to authenticate to GeoServer:
    - urlPattern : is a regular expression that identifies the request url where to apply the rule
    - method : set it to authkey to use the authentication filter you just created in Geoserver.
    - authkeyParamName : is the name of the authkey parameter defined in GeoServer (set to authkey by default)

### Advantages of user integration

Integrating the user/groups database with GeoServer you can allow some users to:

- Execute some processes (via WPS security)
- Download data (setting up the WPS download extension to allow/deny certain users to download data)
- Edit Styles (by default allowed only to administrators, but you can change it acting on /rest/ Filter Chains).
- Access to layers based on users (using the standard GeoServer security)
- Filter layers data based on users (GeoFence), see here
- Allow editing of layers to certain MapStore users (GeoServer Security). The editing can be enabled in the plugin settings of MapStore

## GeoServer Plugins and Extensions

MapStore supports several plugins for GeoServer. Installing them will expand the functionalities of MapStore, allowing to navigate data with time dimension, styling layers and so on.

Here a list of the extensions that MapStore can use:

- WMTS Multidimensional despite the name, this service provides multidimensional discovery services for GeoServer in general, not only for WMTS, and it is **required** to use the timeline plugin of MapStore.
- SLD Rest Service: This extension can be used by the MapStore styler to classify Vector and Raster data. It can inspect the real layer data to apply classification based on values contained in it. It allows to select various classification types (quantile, equalInterval, standardDeviation...) and to customize the color scales based on parameters
- CSS Extension: With this extension the MapStore styler allows to edit styles also in CSS format, in addition to the standard SLD format

• WPS Extension: Provides several process that can be executed using the OGC WPS Standard. IT contains some default services very useful for MapStore:

- **gs:PagedUnique**: Provide a way to query layer attribute values with pagination and filtering by unique values. It enables autocomplete of attribute values for feature grid, attribute table, filter layer and other plugins.
- **gs:Aggregate**: Allows aggregation operation on vector layers. This can be used by the charts (widgets, dashboards) to catch data
- **gs:Bounds**: allows to calculate bounds of a filtered layer, used to dynamically zoom in dashboards map, when filtering is active.
- WPS download community module: This additional module allows to improve the default download plugin, based on WFS, with more functionalities. The advanced Download, activated when GeoServer provides the WPS service above, allows to
  - Download also the raster data
  - Schedule download processes in a download list (and download them later, when post processing is finished).
  - Select Spatial reference system
  - · Crop dataset to current viewport
  - · For vector layers:
    - Filter the dataset (based on MapStore filter)
  - For raster layers:
    - · Select Compression type and quality
    - · Define width and height of internal tiles
- CSW Extension: Activating this extension, MapStore can browse data of GeoServer using the CSW protocol. This is particularly useful when GeoServer contains hundreds or thousands of layers, so the WMS capabilities services can be too slow.
- Query Layer Plugin: This plugin allows the possibility to do cross-layer filtering. Cross layer filtering is the mechanism of Filtering a layer using

geometries coming from another layer. The plugin allows this filtering to be performed on the server side in an efficient way.

 DDS/BIL Plugin: this plugin add to geoserver the possibility to publish raster data in DDS/BIL format (World Wind). This particular plugin is useful if we want to use a raster data as elevation model for MapStore. This elevation model will be used in 3D mode or with the mouse coordinates plugin (displaying the elevation of a point on the map, together with the coordinates).

# LDAP integration with MapStore

The purpose of this guide is to explain how to configure MapStore to use an LDAP repository for authentication and accounting (users, roles and usergroups) instead of the standard database.

## Overview

By default the MapStore backend users service (also known as GeoStore), uses a relational database to store and fetch users details, implement authentication and assign resource access rights to users and groups (for maps, dashboards, etc.).

If you already have your users on an LDAP repository you can anyway configure MapStore to connect to your service and use it to authenticate users and associate user groups and roles, instead of using the default database. In this case the relational database will store only resources and accessory data (permissions, attributes ...) referring the users of your service.

Notice that the LDAP storage is read-only. This means that the MapStore User/ Groups management UI cannot be used to manage users and groups. This makes sense because an LDAP repository is considered an external source and should be managed externally.

If this can create confusion, you can eventually fully disable the UI when using LDAP, by removing the corresponding plugin from the MapStore configuration.

The LDAP storage can be configured in two different ways:

- synchronized mode
- direct connection mode (experimental)

### Synchronized mode

In *synchronized mode*, user data (users, groups, roles) is read from LDAP on every login and copied on the internal database.

Any other operation, for example getting user permissions on maps, always uses the internal database.

Synchronized mode is faster for normal use, but data may disalign when users are removed from the LDAP repository.

In general we suggest to use synchronized mode, since it is the most stable and tested one.

### Direct connection mode (experimental)

In direct connection mode, user data is always read from LDAP, for any operation, so there is no risk of misaligned data.

Direct connection is still experimental and not tested in all the possible scenarios, but will hopefully become the standard mode in an early future, because the approach is simpler and avoids most the synchronized mode defects (e.g. misalignments).

## Configuration

Configuring MapStore to use the LDAP storage requires:

- filling out the LDAP configuration properties in the java/web/src/main/ resources/Idap.properties file to match your LDAP repository structure
- invoking the build with the Idap profile

./build.sh <version> ldap

### Configuration properties

Configurable properties in the Idap.properties file include the following:

## name of the LDAP server host ldap.host=localhost ## port of the LDAP server ldap.port=10389 ## root path for all searches ldap.root=dc=acme.dc=org ## complete DN of an LDAP user, with browse permissions on the used LDAP tree (optional, if browse is available to anoymous users) ldap.userDn= ## password of the userDn LDAP user (optional, if browse is available to anoymous users) ldap.password= ## root path for seaching users ldap.userBase=ou=people ## root path for seaching groups ldap.groupBase=ou=groups ## root path for seaching roles ldap.roleBase=ou=groups ## LDAP filter used to search for a given username  $({0})$  is the username to search for) ldap.userFilter=(uid={0}) ## LDAP filter used to search for groups membership of a given user ({0} is the full user DN) ldap.groupFilter=(member={0}) ## LDAP filter used to search for role membership of a given user ({0} is the full user DN) ldap.roleFilter=(member={0}) ## enables / disables support for nested (hierarchical) groups; when true, a user is assigned groups recursively if its groups belong to other groups ldap.hierachicalGroups=false ## LDAP filter used to search for groups membership of a given group ({0} is the full group DN) ldap.nestedGroupFilter=(member={0}) ## max number of nested groups that are used ldap.nestedGroupLevels=3 ## if true, all the searches are recursive from the relative root path

ldap.searchSubtree=true

```
## if true, all users, groups and roles names are transformed
to uppercase in MapStore
ldap.convertToUpperCase=true
```

### Enabling direct connection mode

The default configuration enables the synchronized mode. To switch to direct connection mode you have to manually edit the final geostore-spring-security.xml to uncomment the related section at the end of the file:

```
<!-- enable direct connection mode -->
<bean id="ldapUserDAO" [...]>
[...]
</bean>
<bean id="ldapUserGroupDAO" [...]>
[...]
</bean>
<!-- -->
```

## Testing LDAP support

If you don't have an LDAP repository at hand, a very light solution for testing is the acme-ldap java server included in the GeoServer LDAP documentation here.

You can easily customize the sample data tree, editing the java code.

The sample MapStore LDAP configuration in the default ldap.properties file works seamlessly with acme-ldap.

## Advanced Configuration

More information about the MapStore backend storage and security service, GeoStore, is available here.

In particular, more information about LDAP usage with GeoStore is in the following Wiki page.

# Integration with OpenID connect

MapStore allows to integrate and login using some common OpenID connect services. Having this support properly configured, you can make MapStore users able to login with the given OpenID service.

## Customizing logo an text in Login Form

For details about the configuration for a specific service, please refer to the specific section below. For details about authenticationProviders optional values (e.g. to customize icon and/or text to show), refer to the documentation of the LoginPlugin.

By default authenticationProviders is {"type": "basic", "provider": "geostore"}, that represents the standard login on **MapStore** with username and password. With the default configuration, when the user try to login, MapStore will show the classic login form.

It is possible to add other providers to the list (e.g. openid) and they will be added as options to the login window. You can remove the geostore entry from authenticationProviders list to remove the login form from the possible login systems.

#### Note

If only one OpenID entry is present in authenticationProviders (and no geostore entry available), clicking on login in the login menu will not show any intermediate window and you will be redirected directly to the OpenID provider configured. If more than one entry is present in authenticationProviders list, the user will have to choose one of them to be authenticated.

## Supported OpenID services

MapStore allows to integrate with the following OpenID providers.

• Google

Keycloak

Note

For each service you want to add you have to:

- properly configure the backend
- modify localConfig.json adding a proper entry to the authenticationProviders.

# For the moment we can configure only one authentication per service type (only one for google, only one for keycloak ...).

### Google

#### Create Oauth 2.0 credentials on Google Console

In order to setup the openID connection you have to setup a project in Google API Console to obtain Oauth 2.0 credentials and configure them.

• Open Google developer console and, from credentials section, create a new credential of type **Oauth client ID** 

	Google Cloud	♣ dev-332916 🗕 🗖	Search Products, resourc	es, docs (/)	~	
API	APIs & Services	Credentials	+ CREATE CREDENTIALS	DELETE		
٩	Enabled API & services	Create credentials to a	API key ac Identifies your projectusing a	a simple API key to check qu	ota and access	
岀	Library	API Keys	OAuth client ID Requests user consent so your app can access the user's data			
0-	Credentials	Name	Service account			
ijΫ	OAuth consent screen	dev	Enables server-to-server, app	-level authentication using ro	obot accounts	
	Domain verification	OAuth 2.0 Client	Help me choose Asks a few questions to help you decide which type of credential to use			
=0	Page usage agreements	Name Name	Creation date 🗸	Туре	Client ID	
		MapStore t	test Jan 25, 2022	Web application	35344056130	
		Service Account	ts			
		Email		Name 个		
		No service account	No service accounts to display			

• Set the **Application Type** to **Web Application**, name it as you prefer and configure the root of the application as an authorized redirect URI. Then click on **Create** 

	ion type *
Name *	
MapSto	re 🔶
	e of your OAuth 2.0 client. This name is only used to identify the client in the and will not be shown to end users.
0	The domains of the URIs you add below will be automatically added to your OAuth consent screen as authorized domains.
	rized JavaScript origins @
	th requests from a browser
or use wi	th requests from a browser
+ ADD	th requests from a browser
+ ADD	th requests from a browser
+ ADD	th requests from a browser URI rized redirect URIs
+ ADD	th requests from a browser URI rized redirect URIs
+ ADD	th requests from a browser URI rized redirect URIs @ th requests from a web server my.site.com/mapstore/

 After creation you will obtain ClientID and Client Secret to use to configure MapStore.

Please follow the Google documentation for any detail or additional configuration.

#### Configure MapStore back-end for Google OpenID

After the setup, you will have to:

• create/edit mapstore-ovr.properties file (in data-dir or class path) to configure the google provider this way:

```
# enables the google OpenID Connect filter
googleOAuth2Config.enabled=true
#clientId and clientSecret
googleOAuth2Config.clientId=<the_client_id_from_google_dev_console</pre>
googleOAuth2Config.clientSecret=<the_client_secret_from_google_dev</pre>
# create the user if not present
googleOAuth2Config.autoCreateUser=true
# Redirect URL
googleOAuth2Config.redirectUri=https://<your-appliction-domain>/
mapstore/rest/geostore/openid/google/callback
# Internal redirect URI (you can set it to relative path like
this `../...` to make this config work across domain)
googleOAuth2Config.internalRedirectUri=https://<your-appliction-</pre>
domain>/mapstore/
## discoveryUrl: contains all the information for the specific
service.
googleOAuth2Config.discoveryUrl=https://
accounts.google.com/.well-known/openid-configuration
```

#### Configure MapStore front-end for Google OpenID

• Add an entry for google in authenticationProviders inside localConfig.json file.

```
{
    "authenticationProviders": [
        {
            "type": "openID",
            "provider": "google"
        },
        {
            "type": "basic",
        }
}
```

```
"provider": "geostore"
}
]
}
```

### Keycloak

Keycloak is an open source identity and access management application widely used. MapStore has the ability to integrate with keycloak:

- Using the standard OpenID Connect (OIDC) protocol to login/logout in MapStore
- Supporting Single Sign On (SSO) with other applications.
- Mapping keycloak roles to MapStore groups, as well as for Idap.

In this section you can see how to configure keycloak as a standard OpenID provider. For other advanced functionalities, you can see the dedicated section of the documentation

#### **Configure keycloak Client**

Create a new Client on keycloak. In this guide we will name it mapstore-server
(because if you need to configure SSO, we may need another key to call
mapstore-client )

nfigure	Lookup 🚱			-	-	
🚻 Realm Setti	Search	Q				Create
🕤 Clients	Client ID	Enabled	Base URL	Actions		
🚓 Client Scopes	account	True	http://localhost:8080/realms/master/account/	Edit	Export	Delete
Roles	account-console	True	http://localhost:8080/realms/master/account/	Edit	Export	Delete
 ⇒ Identity	admin-cli	True	Not defined	Edit	Export	Delete

### Configure MapStore back-end for Keycloak OpenID

Create/edit mapstore-ovr.properties file (in data-dir or class path) to configure the keycloak provider this way:

```
# enables the keycloak OpenID Connect filter
keycloakOAuth2Config.enabled=false
# Configuration
keycloakOAuth2Config.jsonConfig=<copy-here-the-json-config-from-
keycloak-removing-all-the-spaces>
```

```
# Redirect URLs
# - Redirect URL: need to be configured to point to vour
application at the path <base-app-url>/rest/geostore/openid/
keycloak/callback
# e.g. `https://my.mapstore.site.com/mapstore/mapstore/rest/
geostore/openid/keycloak/callback`
keycloakOAuth2Config.redirectUri=https://my.mapstore.site.com/
mapstore/rest/geostore/openid/keycloak/callback
# - Internal redirect URL when logged in (typically the home
page of MapStore, can be relative)
keycloakOAuth2Config.internalRedirectUri=https://
my.mapstore.site.com/mapstore/
# Create user (if you are using local database, this should be
set to true)
keycloak0Auth2Config.autoCreateUser=true
# Comma separated list of <keycloak-role>:<geostore-role>
keycloakOAuth2Config.roleMappings=admin:ADMIN,user:USER
# Comma separated list of <keycloak-role>:<geostore-group>
keycloakOAuth2Config.roleMappings=MY_KEYCLOAK_ROLE:MY_MAPSTORE_GRO
```

# Default role, when no mapping has matched
keycloakOAuth2Config.authenticatedDefaultRole=USER

- keycloakOAuth2Config.jsonConfig:insert the JSON copied, removing all the spaces
- keycloakOAuth2Config.redirectUri: need to be configured to point to your application at the path <base-app-url>/rest/geostore/openid/keycloak/ callback, e.g. https://my.mapstore.site.com/mapstore/rest/geostore/ openid/keycloak/callback
- keycloakOAuth2Config.internalRedirectUri can be set to your application root, e.g. https://my.mapstore.site.com/mapstore/
- keycloak0Auth2Config.autoCreateUser : true if you want MapStore to insert a Keycloak authenticated user on the DB. UserGroups will be inserted as well and kept in synch with the roles defined for the user in Keycloak. The option must be set to false if MapStore is using a read-only external service for users and groups (i.e. Keycloak or LDAP).

- keycloakOAuth2Config.forceConfiguredRedirectURI : optional, if true, forces the redirect URI for callback to be equal to teh redirect URI. This is useful if you have problems logging in behind a proxy, or in dev mode.
- keycloak0Auth2Config.roleMappings : comma separated list of mappings with the following format

keycloak\_admin\_role:ADMIN,keycloak\_user\_role:USER. These mappings
will be used to map Keycloak roles to MapStore roles. Allowed values USER
or ADMIN.

- keycloakOAuth2Config.authenticatedDefaultRole : where the role has not been assigned by the mappings above, the role here will be used. Allowed values USER or ADMIN.
- keycloak0Auth2Config.groupMappings : comma separated list of mappings with the following format

keycloak\_role\_name:mapstore\_group\_name,keycloak\_role\_name2:mapstore\_
These mappings will be used to map Keycloak roles to MapStore groups.

 keycloakOAuth2Config.dropUnmapped : when set to false, MapStore will drop Keycloak roles that are not matched by any mapping role and group mapping. When set to true all the unmatched Keycloak roles will be added as MapStore UserGroups.

#### Configure MapStore front-end for Keycloak OpenID

• Add an entry for keycloak in authenticationProviders inside localConfig.json file.

```
{
    "authenticationProviders": [
        {
            "type": "openID",
            "provider": "keycloak"
        },
        {
            "type": "basic",
            "provider": "geostore"
        }
    ]
}
```

# Keycloak Integrations

# General

MapStore supports various Keycloak integration features:

- **OpenID support**: Allows to login to MapStore using a keycloak account.
- **Single sign on**: Enhances the OpenID support by detecting a session in the keycloak realm and automatically login/logout from MapStore
- **Direct user integration**: Enhances the OpenID support making MapStore use keycloak as unique Identity Manager System (IdM), replacing the MapStore DB with Keycloak REST API.

# OpenID

**Keycloak OpenID support** allows to use a keycloak instance as Identity Provider (IdP) via OpenID Connect (OIDC), so that the user can login to MapStore using an existing account in keycloak.

You can find details about how to configure it in the dedicated "OpenID Connect" page section dedicated to keycloak

# Single sign on integration

MapStore provides an integration with the keycloak **Single Sign On** (SSO) system, that allows to **automatically login/logout** in MapStore when you login/ logout from another application in the same keycloak realm, an vice-versa.

In order to enable the SSO in keycloak you have to:

- Have already configured the openID for keycloak.
- Create a keycloak client in the same realm of openID integration above.
- Configure SSO in MapStore's localConfig.json

## Configure the OpenID integration

• See here openID integration.

# Configure keycloak client

After configuring the open openID integration, you will have a keycloak client called mapstore-server . In order to enable SSO you have to create **another** new Client on keycloak. In this guide we will name it mapstore-client.

onfigure ₩ Realm Setti	Lookup 😡	Toron 1

3	

## Configure SSO in MapStore

After configuring the open openID integration, you will have an entry named keycloak in authenticationProviders. In this entry, you will have to add "sso":{"type":"keycloak"} and config: "<configuration coped from keycloak>".

e.g.

```
{
    "authenticationProviders": [
    {
        "type": "openID",
        "provider": "keycloak",
        "config": {
            "realm": "master",
            "auth-server-url": "http://localhost:8080/",
            "ssl-required": "external",
            "resource": "mapstore-client",
            "public-client": true,
            "confidential-port": 0
        },
        "sso": {
    }
}
```

```
"type": "keycloak"
}
],
}
```

Here implementation details about keycloak login workflow.

# Direct user integration

By default MapStore can integrate openID login with Keycloak and also supports integration with Keycloak SSO.

By default users that login with Keycloak are created on the database and their Keycloak roles inserted as MapStore UserGroup. Anyway MapStore can interact with Keycloak REST API to provide a direct integration without persisting anything on the MapStore's database. This provides a stricter integration between the applications, allowing the assignment of roles and groups directly from keycloak, and avoiding any synchronization issue.

In this scenario the integration MapStore replaces the user and user-group database tables with the keycloak REST API.

This integration disables reading and writing to the users' and groups' database and replaces it with the Keycloak REST API, with read-only support. For this reason we suggest to disable the UserManager, GroupManager plugins, and remove the authenticationProviders entry of type geostore, if any, because the standard login with username and password is not allowed for the db users. In case of integration with GeoServer, also GeoServer should be connected to Keycloak for users, and not to the MapStore database.

## Configure direct integration with keycloak

To enable the direct integration with keycloak you will have to:

- 1. Create a dedicated client for keycloak.
- 2. Configure mapstore-ovr.properties

3. Activate the functionality via system property

#### **1. Create a dedicated client for keycloak**

• Create **another** client on keycloak, in the same realm of mapstore-server and mapstore-client (where present) called mapstore-users:

Master 🗸 🧭	lients					
Configure	Lookup 📀			-		
W Realm Setting					1	
~ ~ ~	Search	Q				Create

OAuth 2.0 Device Authorization Grant Enabled @	OFF		
Front Channel Logout @	OFF	/	
Root URL @			
* Valid Redirect	http://localhost:8081/*		_

#### And click on Save.

#### 2. Configure mapstore-ovr.properties

The autoCreateUser option must be set to false in mapstore-ovr.properties.

keycloak0Auth2Config.autoCreateUser=false

Moreover in mapstore-ovr.properties you have to add the following information (replacing <keycloak-base-url> with your base keycloak base url):

```
## Keycloak as User and UserGroup repository
keycloakRESTClient.serverUrl=<keycloak-base-url>
keycloakRESTClient.realm=master
keycloakRESTClient.username=admin
keycloakRESTClient.password=admin
keycloakRESTClient.clientId=mapstore-users
```

#### Where:

- serverUrl: URL of keycloak, (e.g. http://localhost:8080 or https:// mysite.com/)
- realm : the realm where the client has been created
- username, password: credentials of a user with the role to view-users.<sup>1</sup>

<sup>1</sup> In order to query the keycloak REST API, you need to have in your realm at least one user with realm-admin role permission. Usually the administrator of the realm has these permission. To associate these permissions to a new user dedicated to this purpose, you have to open "Role Mappings" tab of keycloak and in "Client Roles" select realm-management (or in master realm select master-realm) and add to selected realm-admin.

#### 3. Activate the functionality via system property

In order to activate the integration in your instance, you will need to set the Java System Property security.integration with the value keycloak-direct.

One easy and usual way to configure this system property in Tomcat is using the JAVA\_OPTS . Like you do with datadir.location , you can set it by adding to JAVA\_OPTS variable the entry -Dsecurity.integration=keycloak-direct.

```
Note
For old projects or in case you can not set the system property, you can anyway configure it by
adding this section to your geostore-spring-security.xml file.
       <bean
           id="keycloakUserGroupDA0"
   class="it.geosolutions.geostore.services.rest.security.keycloak.KeycloakUserGr
           <constructor-arg ref="keycloakRESTClient"/>
           <property name="addEveryOneGroup" value="true"/>
       </bean>
       <alias name="keycloakUserDAO" alias="userDAO"/>
       <bean
           id="keycloakUserGroupDA0"
   class="it.geosolutions.geostore.services.rest.security.keycloak.KeycloakUserGr
           <constructor-arg ref="keycloakRESTClient"/>
       </bean>
       <alias name="keycloakUserGroupDAO" alias="userGroupDAO"
   addEveryOneGroup="true"/>
       <alias name="externalSecurityDAO" alias="securityDAO"/>
```

# SSO Workflow in Keycloak

Here in this section some details about keycloak SSO integration

# Desired workflow

If keycloak SSO is configured, we want to implement the following workflow.

The keycloakJS library implements the following workflow:

MapStore can:

- Re-run init
- Intercept onAuthLogout
- Implement adapter methods login, logout.
- Intercept init promise resolve with . then

Note

changed is the variable emitted by an internal iframe managed by the keycloak JS API. This technique allows to intercept logout events, anyway refreshing tokens or intercepting login, after first attempt doesn't seem to work well and has some limitations because of security reasons. In particular in the current implementation with <code>openID</code> sync with GeoStore we need to workaround partially the logic of the library to make the tokens work in sync.

# Implementation

The SSO integration in MapStore will reuse the entry points of the JS lib together with the existing openID integration in keycloak, implementing the following workflows:

### Initialization

At the initial page load, we check if the authenticationProviders contains a sso entry (only keycloak)

- LoadJS: loads keycloak.js, that includes the JS support to keycloak, from keycloak instance (only once)
- Init is initialized by MapStore with the current config, adding MapStore's access\_token and refresh\_token, if present, from openID login.

## Monitoring phase

After initialization, we may receive different events or cases. These are the possible cases:

#### Case 1 - Login From MapStore

If MapStore is not logged in, the user can click on login button and be redirected to keycloak login form. After that, the init flow will pass the MapStore tokens to the JS interface. They will be used to check session logout.

#### Case 2 - Login from keycloak

If MapStore is not logged in, the init function do a check-sso operation and finish. In order to monitor the login on MapStore, we implemented a timer to reinit trigger anytime the check-sso resolves with not authenticated.

Implementation is using messageReceiveTimeout as timeout, the same timeout variable of the keycloak JS library for monitoring logout

#### Case 3 - Logout from keycloak

In this case the library that receives a valid keycloak token monitors the logout autonomously.

#### Case 4 - Logout from MapStore

Logout from MapStore, a bug in keycloak API doesn't correctly check the internal iframe (changed option event), and there is no possibility to trigger it, until you visit the keycloak page. This condition after logout can not be distinguished from a external login (from keycloak) detection. So refreshing the page before the token on client is naturally expired will cause a redirect to Login page, because MapStore find there is an active session on keycloak. In order to avoid this, an hack is necessary. MapStore loads an iframe immediately after logout to allow the cookie session to be catch and to apply the proper reset.

## Refresh token

By default keycloak has 5 minutes long lifetime for token, 30 minutes for refresh token. Anyway this can be configured. For this reason, the keycloak support schedules a refresh based on the current token expiration, restarting from init, scheduling a refresh as half of time between expiring time and now. (e.g The token expires 2 minutes from now, a refresh is scheduled in 1 minute).

# MapStore Authentication - Implementation Details

In this section you can see the implementation details about the login / logout workflow implemented by MapStore.

# Standard MapStore login

# OpenID MapStore Login

# Possible setups

Accordingly with your infrastructure, there are several setups you can imagine with MapStore and GeoServer.

MapStore-GeoServer integration

# MapStore-LDAP + MapStore-GeoServer

MapStore-GeoServer + MapStore-LDAP + GeoServer-LDAP

# MapStore-GeoServer + MapStore-LDAP (direct) + GeoServer-LDAP

# MapStore Projects

MapStore projects can be created using the Project Creation Script.

A MapStore project is a custom WebGis application that uses MapStore as a framework.

The MapStore framework is linked as a git submodule in the MapStore2 project subfolder.

Since MapStore is linked as a submodule, every project custom file should be created outside of it. This allows updating MapStore to a newer version easily, without conflicts. The general rule is: **never add / update / modify files directly in the MapStore2 subfolder**.

# Standard Projects

A **Standard** MapStore project is a project that is, initially, a perfect copy of the standard MapStore product.

To create custom application using the standard projects template, you will start from **js/app.jsx** that is the project entry point.

Editing **app.jsx** you can start using your own configuration files and add custom behaviours and look and feel to your project, in particular:

You can add your own translation files. Setting an array of paths in the translationsPath, the resources will be loaded in cascade from every directory of the array. So you can keep all the original translations from MapStore (first element of the array) and add your own files in the directory translations, overriding original values of the json or adding new ones (for instance, for your custom plugins). The files in the new directory must follow the same naming convention of the files in the original directory.

```
ConfigUtils.setConfigProp("translationsPath", ["./MapStore2/web/
client/translations", "./translations"]);
```

• Use your own configuration file for plugins and other configurations. You can copy the original localConfig.json in the root of the project and configure the application to load it (instead of the default one, located in MapStore2/web/client/localConfig.json).

ConfigUtils.setLocalConfigurationFile("localConfig.json");

or you can apply some patch files defining an array of configurations, where the first is the main json file, and the rest are the patch files which must end with "patch.json" in the filename

```
ConfigUtils.setLocalConfigurationFile(["localConfig.json",
"production.patch.json"]);
```

the patch will be applied using this package

Configure your own pages:

```
import productAppConfig from "@mapstore/product/appConfig";
import MapViewer from "@mapstore/product/pages/MapViewer";
const appConfig = {
    ...productAppConfig,
    pages: [{
        name: "mapviewer",
        path: "/",
        component: MapViewer
    }]
};
```

 Include the plugins you want in the app (either MapStore plugins or your own):

# Organizing your code

Our convention is to use the **js** folder to store your project code. You should recreate inside it the usual folders to organize your code based on the source code type:

- components
- actions
- reducers
- epics
- plugins

Images and other static assets should be located in the **assets** folder instead.

# Create your own MapStore project

#### Note

From version 2021.02.xx MapStore introduced a new project system. Take a look here to learn more about the new project system.

To create a new MapStore based project you can use the createProject script. First of all, if you don't have done it before, clone the MapStore2 repository master branch into a local folder:

git clone https://github.com/geosolutions-it/MapStore2

Then, move into the folder that has just been created, containing MapStore2:

cd MapStore2

Choose from which branch you want the mapstore revision to be aligned, we suggest to use latest release or latest stable available (if you know which is)

git checkout <stable-branch>

or

git checkout v2022.02.02

Install dependencies for MapStore:

npm install

Finally, to create the project, use the following command:

```
<projectVersion> <projectType> <projectName> <projectVersion> <projectDescription> <gitRepositoryUrl> <outputFolder>
```

Note that projectName and outputFolder are mandatory:

- projectName: short project name that will be used as the repository name on github, webapp path and name in package.json
- projectType: type of project to create, currently one type of projects is supported:
- standard: is a copy of the standard MapStore project, ready to be used and customized
- projectVersion: project version in package.json (X.Y.Z)
- projectDescription: project description, used in sample index page and as description in package.json
- gitRepositoryUrI: full url to the github repository where the project will be published
- outputFolder: folder where the project will be created

Usage:

```
node ./createProject.js standard MyProject "1.0.0" "this is my
awesome project" "" ../MY_PROJECT_NAME
```

At the end of the script execution, the given outputFolder will be populated by all the configuration files needed to start working on the project. Moreover, the local git repository will be initialized and the MapStore sub-module added and downloaded.

If you create a *standard* project, you can customize it editing **js/app.jsx**: look at the comments for hints and the MapStore documentation for more details.

The following steps are:

npm install to download dependencies

- npm start to test the project
- ./build.sh to build the full .war

# Create a new project type

If you are not happy with the available project types (*standard*), you can extend them adding a new folder in **project**.

The folder will contain two sub-folders:

- static: for static content, to be copied as is to the project folder
- **templates**: for template files, containing project-dependent variables that will be replaced by the createProject script. You can use the following variables:
- \_\_PROJECTNAME\_\_: \<projectName> parameter value
- \_\_PROJECTDESCRIPTION\_: \<projectDescription> parameter value
- \_\_PROJECTVERSION\_\_: \<projectVersion> parameter value
- \_\_REPOURL\_\_: \<gitRepositoryUrl> parameter value

In addition to static and templates, the following files from the root MapStore folder will be copied:

- .babelrc
- .editorconfig
- LICENSE.txt

# Update MapStore2 version in a project

To update MapStore2 version enter the MapStore2 folder and pull desired git version. If MapStore2 devDependencies have been changed you can manually update these in the project package.json file or run the script updateDevDeps

npm run updateDevDeps

The script will automatically copy the devDependencies from MapStore2 package.json to the project package.json file. All the project existing devDependencies will be overwritten.

To sync MapStore2 dependencies just run npm install from project root folder.

npm install

Also make sure to follow the migration guidelines here.

# MapStore API usage

You can include MapStore in your application and interact with it via its JavaScript API

## How to use

- 1. Create a map using the standard installation
- 2. Go to Share -> Embed
- 3. Copy the API html code and paste it in your application page

The map will now load inside your application

NOTE: If the map is using a Google Maps background you will have to provide your own API key. Add `&key=YOUR\_API\_KEY` in the <script> src value

# MapViewer query parameters

In this section we will describe the available MapViewer query parameters that can be used when the map is loaded.

MapStore allows to manipulate the map by passing some parameters. This allows external application to open a customized viewer generating these parameters externally. With this functionality you can modify for instance the initial position of the map, the entire map and even trigger some actions.

# Passing parameters to the map

## Get Request

The parameters can be passed in a query-string-like section, after the #<path>? of the request.

Example:

#/viewer/openlayers/new?center=0,0&zoom=5

Note

The parameters in the request should be URL encoded. In order to make them more readable, the examples in this page will now apply the URL encoding.

## **POST Request**

Sometimes the request parameters can be too big to be passed in the URL, for instance when dealing with an entire map, or complex data. To overcome this kind of situations, an adhoc POST service available at <mapstore-base-path>/ rest/config/setParams allows to pass the parameters in the request payload application/x-www-form-urlencoded. The parameters will be then passed to

the client (using a temporary queryParams-{random-UUID} variable in sessionStorage). Near the parameters, an additional page value can be passed together with the params to specify to which url be redirect. If no page attribute is specified by default redirection happens to #/viewer/openlayers/ config. The UUID used in the queryParams-{random-UUID} variable name is being added to the redirect URL in a query parameter named queryParamsID=. Assuming to use the default redirect value, the url will then look like the following: #/viewer/openlayers/config?queryParamsID={random-UUID}.

Example application/x-www-form-urlencoded request payload (URL encoded):

```
page=..%2F..
%2F%23%2Fviewer%2Fopenlayers%2Fnew&featureinfo=&bbox=&center=1%2C1
```

Here a sample page you can create to test the service:

```
<html><head><meta charset="UTF-8">
    <script>

# Available Parameters

## Feature Info

Allows to trigger identify tool for the coordinates passed in "lat"/"lng" parameters.

Optional parameter "filterNameList" allows limiting request to the specific layer names. It will be effectively used only if it's passed as non-empty array of layer names. Omitting or passing an empty array will have the same effect.

```
GET: #/viewer/openlayers/config?featureinfo={"lat": 43.077, "lng":
12.656, "filterNameList": []}
```

```
GET: #/viewer/openlayers/config?featureinfo={"lat": 43.077, "lng":
12.656, "filterNameList": ["layerName1", "layerName2"]}
```

#### Simplified syntax

GET: #/viewer/openlayers/config?featureInfo=38.72,-95.625

Where lon, lat values are comma-separated respecting order.

### Map

Allows to pass the entire map JSON definition (see the map configuration format of MapStore).

GET:

```
#/viewer/openlayers/config?map={"version":2,"map":
{"projection":"EPSG:900913","units":"m","center":{"x":
1250000,"y":5370000,"crs":"EPSG:900913"},"zoom":5,"maxExtent":
```

```
[-20037508.34,-20037508.34,20037508.34,20037508.34],"layers":
[{"type":"osm","title":"Open Street
Map","name":"mapnik","source":"osm","group":"background","visibili
```

It also allows partial overriding of existing map configuration by passing only specific properties of the root object and/or the internal "map" object.

Following example will override "catalogServices" and "mapInfoConfiguration":

```
#/viewer/openlayers/config?map={"mapInfoConfiguration":
    {"trigger":"click","infoFormat":"text/html"},"catalogServices":
    {"services": {"wms": {"url": "http://example.com/geoserver/
    wms","type": "wms","title": "WMS","autoload":
    true}},"selectedService": "wms"}}
```

## Center / Zoom

GET: #/viewer/openlayers/config?center=0,0&zoom=5

Where lon, lat values are comma-separated respecting order.

## Marker / Zoom

GET: #/viewer/openlayers/config?marker=0,0&zoom=5

Where lon, lat values are comma-separated respecting order.

#### Bbox

GET: #/viewer/openlayers/config?bbox=8,8,53,53

Where values are minLongitude, minLatitude, maxLongitude, maxLatitude respecting order.

#### AddLayers

This is a shortened syntax for CATALOG:ADD\_LAYERS\_FROM\_CATALOGS action described down below.

```
GET: #/viewer/openlayers/config?
addLayers=layer1;service,layer2&layerFilters=attributeLayer1='value';att
```

addLayers parameter is a comma separated list of <layerName>;<service> (service is optional, and if present is separated from the layerName by a ;.

In the example above:

- layer1 and layer2 are layer names;
- service is the service identifier of the catalog. If no service is provided, the default service will be used.
- layerFilters is a list of cql filters to apply to the corresponding layer in the same position of the addLayers parameter, separated by ;

## MapInfo

This is a shortened syntax for SEARCH:SEARCH\_WITH\_FILTER action described down below. In opposite to direct usage of action, mapInfo parameter can work with layers added by addLayers parameter. In this case search execution will be postponed up to the moment when layer is added to the map.

mapInfo handler will check if addLayers parameter is present and if it lists layer name used in mapInfo parameter. If so, it will postpone search to ensure that layer is added to the map. Otherwise, in case of no matches, search will execute immediately.

```
GET: #/viewer/openlayers/new?
addLayers=layer1;service&mapinfo=layer1&mapInfoFilter=BB='cc'
```

Where:

- layer1 is layer name.
- service is the service name providing layer data. Service name is optional. If no service is provided, the default service of the catalog will be used.
- mapInfoFilter is a cql filter applied to the layer.

## Background

Allows to dynamically add background to the map and activate it. Supports default backgrounds provided by static service defined in localConfig.json (default\_map\_backgrounds) as well as other layers:

#/viewer/openlayers/new?background=Sentinel;default\_map\_backgrounds

#/viewer/openlayers/new?background=layer1;service

#/viewer/openlayers/new?background=layer2

Where:

- Sentinel, layer1, layer2 are layer names,
- service, default\_map\_backgrounds are the service names providing layer data. Service name is optional. If no service is provided, the default service of the catalog will be used.

According to the implementation of default\_map\_backgrounds service, it is enough to pass desired layer name even partially, e.g.

background=Sen;default\_map\_backgrounds, it will use the closest layer name match in this case.

## Actions

To dispatch additional actions when the map viewer is started, the **actions** query parameter can be used. Only actions from a configured whitelist can be dispatched in this way (see the configuration section for more details).

```
// list of actions types that are available to be launched
dynamically from query param (#3817)
  "initialActionsWhiteList": ["ZOOM_TO_EXTENT",
  "ADD_LAYER", ...]
```

The value of this parameter is a JSON string containing an array with an object per action. The structure of the object consist of a property type and a bunch of other properties depending on the action.

## Available actions

Only the following actions can be used in the **actions** json string.

#### Zoom to extent

It zooms the map to the defined extent.

Example:

```
{
    "type": "Z00M_T0_EXTENT",
    "extent": [1,2,3,4],
    "crs": "EPSG:4326",
    "maxZoom": 8
}
```

```
GET: #/viewer/openlayers/config?actions=[{"type":
"ZOOM_TO_EXTENT","extent": [1,2,3,4],"crs": "EPSG:4326","maxZoom":
8}]
```

For more details check out the zoomToExtent in the framework documentation.

#### Map info

It performs a GetFeature request on the specified layer and then a GetFeatureInfo by taking a point from the retrieved features's geometry. This action can be used only for existing maps (map previously created).

With the GetFeature request it takes the first coordinate of the geometry of the first retrieved feature; that coordinates are then used for an usual GFI (WMS GetFeatureInfo) request by limiting it to the specified layer.

A **cql\_filter** is also **mandatory** for that action to properly filter required data: that filter will be used in both request (GetFeature and GFI). If you don't need to apply a filter, you can use the standard INCLUDE clause (cql\_filter=INCLUDE) so the whole dataset will be queried.

Requirements:

- The layer specified must be visible in the map
- There must be a geometry that can be retrieved from the GetFeature request

Example:

```
{
    "type": "SEARCH:SEARCH_WITH_FILTER",
    "cql_filter": "ID=75",
    "layer": "WORKSPACE:LAYER_NAME"
}
```

GET: #/viewer/openlayers/config?

actions=[{"type":"SEARCH:SEARCH\_WITH\_FILTER","cql\_filter":"ID=75","layer

The sample request below illustrates how two actions can be concatenated:

```
https://dev-mapstore.geosolutionsgroup.com/mapstore/#/viewer/
openlayers/4093?
actions=[{"type":"SEARCH:SEARCH_WITH_FILTER","cql_filter":"STATE_F
{"type":"Z00M_T0_EXTENT","extent":
[-77.48202256347649,38.74612266051003,-72.20858506347648,40.666647
4326","maxZoom":8}]
```

The MapStore invocation URL above executes the following operations:

- Execution of a search request filtering by **STATE\_FIPS** with value 34 on the **topp:states** layer
- · Execution of a map zoom to the provided extent

For more details check out the searchLayerWithFilter in the framework documentation

#### Scheduled Map Info

It works similarly to the Map Info action, but supports delaying of the search execution up to the moment when layer is added to the map. This behavior is used when search should be applied to the dynamically added layer (e.g. using addLayer parameter):

Example:

```
{
    "type": "SEARCH:SCHEDULE_SEARCH_WITH_FILTER",
    "cql_filter": "ID=75",
    "layer": "WORKSPACE:LAYER_NAME"
}
```

#### GET: #/viewer/openlayers/config?

```
actions=[{"type":"SEARCH:SCHEDULE_SEARCH_WITH_FILTER","cql_filter":"ID=7
{"type":"CATALOG:ADD_LAYERS_FROM_CATALOGS","layers":
["WORKSPACE:LAYER_NAME"],"sources":["catalog1"]}]
```

#### Add Layers

This action allows to add layers directly to the map by taking them from the catalogs configured, or passed.

Requirements:

- The number of layers should match the number of sources
- The source name can be a string that must match a catalog service name present in the map or an object that defines an external catalog (see example)

Supported layer types are WMS, WMTS, WFS and 3D Tiles.

Example:

```
{
    "type": "CATALOG:ADD_LAYERS_FROM_CATALOGS",
    "layers": ["workspace1:layer1", "workspace2:layer2",
```

```
"workspace:externallayername"],
    "sources": ["catalog1", "catalog2",
    {"type":"WMS","url":"https://example.com/wms"}]
}
```

```
GET: #/viewer/openlayers/config?
actions=[{"type":"CATALOG:ADD_LAYERS_FROM_CATALOGS","layers":
["layer1", "layer2", "workspace:externallayername"],"sources":
["catalog1", "catalog2", {"type":"WMS","url":"https://example.com/
wms"}]}]
```

Data of resulting layer can be additionally filtered by passing "CQL\_FILTER" into the options array. Each element of array corresponds to the layer defined in action:

```
{
    "type": "CATALOG:ADD_LAYERS_FROM_CATALOGS",
    "layers": ["workspace1:layer1", "workspace2:layer2",
"workspace:externallayername"],
    "sources": ["catalog1", "catalog2",
{"type":"WMS","url":"https://example.com/wms"}],
    "options": [{"params":{"CQL_FILTER":"NAME='value'"}}, {},
{"params":{"CQL_FILTER":"NAME='value2'"}}]
}
```

#### GET #/viewer/openlayers/config?

```
actions=[{"type":"CATALOG:ADD_LAYERS_FROM_CATALOGS","layers":
["layer1","layer2","workspace:externallayername"],"sources":
["catalog1","catalog2",{"type":"WMS","url":"https://example.com/
wms"}],"options": [{"params":{"CQL_FILTER":"NAME='value'"}}, {},
{"params":{"CQL_FILTER":"NAME='value2'"}}]
```

Number of objects passed to the options can be different to the number of layers, in this case options will be applied to the first X layers, where X is the length of options array.

The 3D tiles service endpoint does not contain a default property for the name of the layer and it returns only a single record for this reason the name used in the layers array will be used to apply the title to the added 3D Tiles layer:

```
{
    "type": "CATALOG:ADD_LAYERS_FROM_CATALOGS",
    "layers": ["My 3D Tiles Layer"],
    "sources": [{ "type":"3dtiles", "url":"https://example.com/
tileset-pathname/tileset.json" }]
}
```

```
GET: #/viewer/config?
actions=[{"type":"CATALOG:ADD_LAYERS_FROM_CATALOGS","layers":["My 3D
Tiles Layer"],"sources":[{"type":"3dtiles","url":"https://example.com/
tileset-pathname/tileset.json"}]
```

For the 3D Tiles you can pass also the layer options, to customize the layer. Here and example to localize the title:

```
{
    "type": "CATALOG:ADD_LAYERS_FROM_CATALOGS",
    "layers": ["My 3D Tiles Layer"],
    "sources": [{ "type":"3dtiles", "url":"https://example.com/
tileset-pathname/tileset.json" }],
    "options":[{ "title": { "en-US": "LayerTitle", "it-IT":
    "TitoloLivello" }}]
}
```

#### GET: #/viewer/config?

```
actions=[{"type":"CATALOG:ADD_LAYERS_FROM_CATALOGS","layers":["My 3D
Tiles Layer"],"sources":[{"type":"3dtiles","url":"https://example.com/
tileset-pathname/tileset.json"}],"options":[{"title":{"en-
US":"LayerTitle","it-IT":"TitoloLivello"}}]
```

# Quick Start

You can either choose to download a standalone binary package or a WAR file to quickly start playing with MapStore.

# Binary package

The easiest way to try out MapStore is to download and extract the binary package available on MapStore release page. Here you can find some preconfigured maps as well users and groups. The goal for this package is to ease all the requirements needed for you to take MapStore for a test-drive.

We hope you enjoy MapStore!

# How to run

Go to the location where you saved the zip file, unzip the contents and run:

Windows: mapstore2\_startup.bat

Linux: ./mapstore2\_startup.sh

Point your browser to: http://localhost:8082/mapstore

To stop MapStore simply do:

Windows: mapstore2\_shutdown.bat

Linux: ./mapstore2\_shutdown.sh

# Package Contents

- MapStore
- Tomcat8

• Java JRE (Win and Linux)

# Demo Maps

- Aerial Imagery Simple map demo showing some aerial imagery data
- WFS Query Map Demo map configured with MapStore built-in ability to query feature over WFS
- User Map and User1 Map Map only visible to *user* and *user1* respectively, to demonstrate MapStore capabilities on user/group management and permissions.

# Demo accounts/groups

Users	Groups
admin/admin	MyGroupAdmin,everyone
guest	everyone
user/user	everyone
user1/user1	everyone, MyGroup

# WAR file

Download the WAR file from the latest release here.

#### All the releases

After downloading the MapStore war file, install it in your java web container (e.g. Tomcat), with usual procedures for the container (normally you only need to copy the war file in the webapps subfolder).

If you don't have a java web container you can download Apache Tomcat from here and install it. You will also need a Java7 JRE.

Then you can access MapStore using the following URL (assuming the web container is on the standard 8080 port):

### http://localhost:8080/mapstore

Use the default credentials (admin / admin) to login and start creating your maps!
